Orbital varices and orbital wall defects

Orbital varices are a vascular hamartoma typified by a plexus of low pressure, low flow, thin walled and distensible vessels that intermingle with the normal orbital vessels.\(^1\)\(^-\)\(^4\) If freely communicating with the orbital circulation, engorgement of varices can occur by increasing venous pressure through the Valsalva manoeuvre,\(^5\) bending posture,\(^6\) coughing or straining and these, in turn, lead to the clinical characteristics of variable proptosis, intermittent pain, and orbital haemorrhage.\(^7\)\(^-\)\(^8\)

Observation is usually warranted for small lesions, but surgical intervention may be necessary in advanced cases: indications for surgical intervention include non-resolving episodes of thrombosis, severe disfiguring proptosis or displacement of the globe, and optic nerve compression.\(^9\)\(^-\)\(^10\) Surgery can be extremely difficult, as varices are very friable and intimately intermixed with normal orbital structures; there is also a significant risk of visual loss as a result of haemorrhage or optic nerve damage, the latter being generally caused by vascular compromise.\(^9\)\(^-\)\(^10\) The association of orbital venous anomalies with orbital wall defects provides a further source of surgical difficulty because of the close proximity of intracranial structures and the continuity with extraorbital or intracranial venous anomalies.

Case series

The orbital database, at Moorfields Eye Hospital, was used to identify patients with a clinical diagnosis of low pressure orbital varices and their orbital imaging (computed tomography and/or magnetic resonance imaging) was reviewed. Images were examined for evidence of orbital expansion, osseous defects of the orbit, nose or sinuses, and anomalies of the frontal lobes. Patients who had either orbital or intracranial surgery before the date of imaging were excluded from the investigation.

The clinical diagnosis of orbital varices was identified in 310 patients, and imaging was available for 223 patients (72%). Six patients with previous orbital or intracranial surgery were excluded and nine cases (4%) had associated anomalies of the neighbouring orbital walls (table 1).

Four cases (patients 1–4) were associated with “pitting” of the orbital wall secondary to orbital varices (fig 1A). Another three cases (patients 6–8) were associated with enlarged superior orbital fissure and two cases (patients 5 and 9) with multiple orbital roof “defects” (fig 1B). Orbital varices were present up to the dural space in two cases (patients 4 and 5), and involved the frontal lobe parenchyma in one case (patient 6; fig 1C, D).

Figure 1  (A) (Patient 1) Extensive left orbital varices (white arrows) causing orbital expansion, globe displacement, and “pitting” of the orbital roof and lamina papryracea (black arrows).  (B) (Patient 5) Bilateral orbital varices associated with multiple defects, rather than pitting, of the orbital walls.  (C) (Patient 6) Right orbital varices, with phleboliths, extending through the orbital apex into the middle cranial fossa (white arrows) and  (D) associated with intracranial bone “pitting” and “defects” (black arrows).  (E) Coronal and (F) axial CT scans of patient 2 with superonasal varices (white arrows) of right orbit in 1981.  (G–J) Repeat coronal and axial CT scans in 2001 show significant enlargement of the bone defect with complete loss of mineralisation, and expansion of the frontal lobe meninges into the orbital wall defect (black arrow).
One patient (case 2) had thinning of the superonasal quadrant of the orbit, nasal orbital wall pitting, and a low ipsilateral cribriform plate, when first seen at age 21 in 1981 (fig 1E, F). On repeat imaging 20 years later (2001), this patient was noted to have developed proptosis, a defect in the superonasal quadrant of the orbit, and a new mid-line nasal encephalocele (fig 1I, J).

The exophytic tumour of patient 2 was predominantly intraepithelial with foci of subepithelial invasion. Focal tumour anaplasia was observed in the otherwise moderately differentiated tumour with squamous cell differentiation.

Immunostaining of both specimens revealed strong p53 (monoclonal mouse-anti-human p53-protein DO-7, Dako) overexpression (>26% of epithelium cells) and low expression of p21 (<6% of epithelium cells) of the invasive region of the tumour indicating an inactivating p53 mutation (fig 1C). While in patient 1 expression for p53 was found in all epithelial layers, in patient 2 it was expressed suprabasally. In contrast, both p53 and p21 showed moderate reactivity in the dysplastic region up to the middle layer of the tumour (fig 1D). In the apical layer epithelial cells were occasionally p21 positive.

Immunostaining for HPV (HPV screening antibody, Virofem Diagnostica, Germany) was positive in patient 1.

Previous biopsies had revealed conjunctival dysplasia. On examination, the tumour of the ocular and tarsal conjunctiva of the lower lid covered the entire corneal surface (fig 1A).

Patient 2

A 90 year old patient presented with a 2 year history of an extensive conjunctival papillomatous tumour of the left eye covering three quarters of the cornea with visual acuity of light perception. A full thickness biopsy was performed.

Both patients underwent orbital exenteration including removal of the eyelids. Histopathologically the focal invasive, completely removed tumour of patient 1 grew in a papillomatous manner. The tumour cells of the conjunctival neoplasm showed strongly enlarged nuclei with prominent nucleoli, and formed cohesive units with intercellular bridges (fig 1B).

Comment

Fine cut (3 mm) orbital CT scans easily delineate varices and diagnostic phleboliths, which occur from thrombus formation, and provide an excellent natural contrast between brain, bone, and varix. The typical findings for varices include an ill defined multiloculated mass, with some patchy contrast enhancement, in communication with the neighbouring orbital circulation; diffuse expansion of the orbital walls is well recognised in some cases, especially in childhood lesions.

Several factors may have biased the study population: many are symptomatic patients, having been referred from other ophthalmic units in consideration for surgical intervention. The apparent incidence of orbital wall defects (4%) in our series may, therefore, be a selection. The apparent incidence of orbital wall defects (4%) in our series may, therefore, be a selection. The apparent incidence of orbital wall defects (4%) in our series may, therefore, be a selection. The apparent incidence of orbital wall defects (4%) in our series may, therefore, be a selection.

to be possible cofactors involved in initiation and early progression of OSSN.4-7 Though both of the presented tumours were clinically papillomatous, immunostaining for HPV was positive only in patient 1. The tumour suppressor gene p53 has been found to be inactivated in over 50% of human cancers. In OSSN, overexpression of p53 has been previously reported in some SCC of conjunctiva.4-7 In the SCC of our patients, p53 overexpression indicating inactivating p53 mutations were observed only in the invasive part of the tumour, but not in the carcinoma in situ. While Dushku and coworkers assumed that p53 mutations could be an early event in tumour development consistent with ultraviolet radiation, our findings clearly indicate that mutations of p53 are a late event that occur with disease progression, as observed with other solid tumours.4-7 Karcoglu and associates found a correlation between p53 overexpression and unfavourable clinical course.4 In contrast, Aoki and colleagues found no expression for p53 in SCC but positive staining in dysplasia.

Our results of two exenterated advanced stages of SCC emphasise the necessity to remove dysplastic OSSN completely to prevent progression to invasive carcinomas. Identification of inactivating p53 mutations may indicate an increased risk for invasiveness. Therefore immunohistochemical analysis of biopsy specimen may help in the management of these tumours.

Familial pseudotumoral sclerochoroidal calcification associated with chondrocalcinosis

Sclerochoroidal calcification is the deposition of calcium at the level of the sclera and choroid. Two entities have been described: metastatic calcifications resulting from deposition of calcium in normal tissues caused by phosphocalcic metabolism abnormality such as primary and secondary hyperparathyroidism,7 pseudohypoparathyroidism,8 hyperparathyroidism,9 hypervitaminose D, vitamin D intoxication, hypophosphataemia, sarcoidosis, Bartter syndrome, and Gietelman syndrome10; and dystrophic calcifications caused by secondary deposition of calcium in abnormal tissues despite normal serum levels of calcium and phosphate.

Sclerochoroidal calcifications can also be idiopathic.11 We describe the first case of hereditary form of sclerochoroidal calcifications associated with familial articular chondrocalcinosis.

Case report

A 69 year old man was admitted to the department of ophthalmology in November 1999 with gradual deterioration of vision in both eyes. He had a medical history of familial chondrocalcinosis. His father, brother, and son were treated for the same disease.

On examination, best corrected visual acuity was 20/120 in the right eye and finger counting in the left eye. Slit lamp examination and ocular tension were normal. The funduscopy revealed multiple bilateral pseudotumoral white choroidal masses in both eyes (fig 1). Ultrasound examination of the eyes confirmed the calcific nature of the lesions.

On fluorescein angiography in March 1979 the pseudotumoral lesions were smaller and did not involve the macular area in left eye (fig 1, left).

He had an extensive metabolic evaluation in the Broussais department of physiology associated with familial articular chondrocalcinosis. His father, brother, and son were treated for the same disease.

We decided to examine the whole family to search for ophthalmic abnormalities linked with familial chondrocalcinosis.

The 74 year old brother and the 40 year old son also suffered from chronic articular chondrocalcinosis. Their best visual acuity was 20/20 in both eyes.

Figure 1 Patient 1. (A) Extensive papillomatous tumour, subtotally covering the corneal surface of the left eye. Nodular thickening of the lower eyelid indicates eyelid involvement. (B) Histological appearance. Papillomatous pattern of the large epithelial lesion with focal invasion above the cornea. Subepithelially, inflammatory cells and some dilated vessels (haematoxylin and eosin, original magnification, ×2.5). (C) p53, showing strong diffuse reactivity in invasive region indicating an inactivating p53 mutation (original magnification, ×10). (D) p53, showing moderate expression predominately in the suprabasal layers in dysplastic conjunctiva of the same specimen (original magnification, ×10).
The brother’s funduscopy revealed multiple bilateral, extrafoveal pseudotumoral white choroidal masses (fig 2, top). The son’s funduscopy revealed plaque-like and only slightly elevated lesions seen in the midperiphery (fig 2, bottom). Ultrasonograms confirmed the calcific nature of these lesions.

Comment
In 1997, Shields et al described a case of sclerochoroidal calcifications in a normocalaemic patient who had chondrocalcinosis. We first describe a familial case of sclerochoroidal calcifications associated with calcium pyrophosphate dihydrate (CPPD). In this family, autosomal dominant inheritance is highly likely because there are affected individuals in each generation, there is male to male transmission, and every affected member has an affected parent.

Inheritance in sclerochoroidal calcifications has never been described; however, hereditary forms of chondrocalcinosis have already been described.

In our report, a patient had a 24 year follow up showing a progressive involvement of the macular area, suggesting a growth of the calcifications. Two types of calcifications have been described previously, the plaque-like and the pseudotumoral type.

To our knowledge, it has never been determined if the plaque-like lesions evolve into tumour-like lesions. In 1992, Schachat and associates reported 10 cases with follow up ranging from 7 months to 10 years, for whom no change in the lesion was seen. This is the first observation with 24 years of follow up suggesting a possible evolution of plaque-like lesions to pseudotumoral lesions.

We suggest that every patient affected by familial chondrocalcinosis should have an ophthalmic examination to detect sclerochoroidal calcification. These lesions seem to be evolving in time with possible involvement of the macula. Choroidal neovascularisation is also a vision threatening complication of sclerochoroidal calcifications. Our case suggests the need to perform ophthalmological examination in patients and family members of patients affected by chondrocalcinosis.

Whole body PET/CT imaging for detection of metastatic choroidal melanoma
Metastatic choroidal melanoma typically presents in the liver. Therefore, liver enzyme assays are the common haematological evaluation performed after treatment.

In 1985, The Collaborative Ocular Melanoma Study required periodic medical evaluations including a physical examination, liver function studies, a complete blood count, a chest x ray. If liver enzymes exceeded 1.5 times normal, computed tomography (CT) of the abdomen was required. If low attenuation hepatic nodules suggested metastatic disease, fine needle aspiration biopsy of the liver tumours provided cytopathological confirmation.

Positron emission tomography (PET) is a molecular imaging technique that uses radiolabelled molecules to image metabolic activity in vivo. When whole body PET was combined with computed radiographic tomography (CT), PET/CT put anatomy and function on the same page making practical a new era of physiological imaging.

This study examines the ability of positron emission tomography combined with computed tomography (PET/CT) to allow for detection of previously occult metastatic melanoma.

Case report
A 77 year old woman presented with a 15.4 x 15 mm width and 13.2 mm high collar button shaped choroidal melanoma with a large secondary retinal detachment in her right eye. Her preoperative medical evaluation...
proved negative. She was treated by enucleation.

Two years later a follow up medical evaluation revealed elevated liver function studies (table 1) and a chest x-ray showed a pleural effusion. CT of the abdomen with contrast revealed multiple low attenuation hepatic foci consistent with metastatic melanoma.

A PET/CT was requested. Fifty minutes after intravenous administration of 15.2 mCi of fluordeoxyglucose, whole body PET/CT imaging revealed enlarged para-aortic lymph nodes and a subcutaneous nodule in the abdominal wall (fig 1). The CT portion of the PET/CT also revealed two 3 mm nodules in the upper lobe of the right lung (too small to be visualised by PET imaging). PET imaging was able to reveal multiple bony metastases that were not seen on the CT portion (fig 1). Both CT and PET showed a large liver metastasis, but CT was better at defining tumour size. Since it is a physiological assay, PET also demonstrated the metabolic activity of the metastatic tumours (fig 1).

Comment
In this case, whole body PET/CT was found to be capable of uncovering metastases not seen with abdominal CT alone. This led us away from considering regional perfusion of the liver, hepatic resection, and towards systemic treatment. Therefore, when PET/CT identifies extrahepatic involvement, it can have a significant impact on the management of patients with metastatic choroidal melanoma.

PET/CT could also be used for initial staging. Early detection of occult metastases

offers the potential to avoid ineffective and expensive enucleations, radioactive plaques, proton irradiation, eye wall resections, or laser treatment. Local therapies would be abandoned in favour of systemic treatments.

Another issue related to PET/CT is cost. Up to five times more than CT of the abdomen, PET/CT is only covered (Medicare) for melanoma staging/restaging when the stage of the cancer remains in doubt after completion of conventional imaging (or if the clinical management would differ depending on the PET findings). Since PET/CT revealed extrahepatic foci in this case, it changed our clinical approach. There is little doubt about hepatic foci in this case, it changed our management would differ depending on the conventional imaging (or if the clinical cancer remains in doubt after completion of melanoma staging/restaging when the stage of the cancer).

Trans-Tenon’s retrobulbar triamcinolone infusion for small choroidal neovascularisation

Intravitreal and sub-Tenon’s corticosteroids are being evaluated for the treatment of choroidal neovascularisation (CNV). We reported on the efficacy of triamcinolone acetate administered as a trans-Tenon’s retrobulbar infusion (triamcinolone infusion) in reducing inflammation in uveitic eyes. Here we evaluated the same treatment in eyes with small subfoveal CNV.

Case reports

Triamcinolone infusion was performed in 22 eyes of 22 patients with subfoveal CNV of greatest diameter less than or equal to 1 disc diameter (DD). The diagnoses were age related macular degeneration (AMD) in 14 eyes, idiopathic CNV in four eyes, polyoid choroidal vasculopathy (PCV) in three eyes, and punctate inner choroidopathy (PIC) in one eye. One AMD eye had undergone ablative argon laser photocoagulation for CNV previously, but no other eyes had received previous treatment. The median post-triamcinolone infusion follow up was 7.5 months (range 4–27 months). Pretreatment fluorescein angiography (FA) revealed predominantly classic CNV in 12 eyes and predominantly occult CNV in 10 eyes. Records were reviewed retrospectively and did not require institutional review board approval. Informed consent was obtained before each procedure.

The patient’s eye was prepared with povidone-iodine and sterile drapes applied. After topical anaesthesia, conjunctiva and Tenon’s capsule were incised in the inferotemporal quadrant. A 23 gauge curved blunt cannula approximately 2.1 cm in length (#HS-2764, Handaya Co, Ltd, Tokyo, Japan) was inserted to the hub into sub-Tenon’s space and 20 mg (0.5 ml) triamcinolone acetate (Bristol Pharmaceutical, KK, Tokyo, Japan) was infused. The wound was left unsutured and 0.5% levofloxacin was instilled topicaly three times a day for 1 week.

Onset of CNV fibrosis was observed in 14 eyes (64%) by 3 months post-triamcinolone infusion (fig 1). Rates of fibrosis were 50% (7/14 eyes) for AMD, 100% (4/4 eyes) for idiopathic CNV, 67% (2/3 eyes) for PCV, and 100% (1/1 eye) for PIC. Fibrosis did not correlate with CNV size or lesion composition. FA performed at 3 months showed decreased lesion leakage in 12 eyes (59%), no change in five eyes (23%), and increased leakage in five eyes (23%). Best corrected visual acuity (VA) at 3 months for all eyes improved by $0.2 logarithm of the minimum angle of resolution (logMAR) in four eyes (18%), remained unchanged in 13 eyes (59%), and worsened by $0.2 logMAR in five eyes (23%). The median decimal VA for all eyes was 0.30 before treatment (range 0.08–1.0) and 0.24 at 3 months after treatment (range 0.05–1.2). Of the 14 eyes with AMD, the VA at 3 months improved by $0.2 logMAR in one eye (7%), remained

Figure 1 Colour fundus photographs and fluorescein angiography late images of an eye in a 65 year old patient with age related macular degeneration and small subfoveal choroidal neovascularisation before (A, B; best corrected visual acuity 0.3) and 3 months after triamcinolone infusion (C, D; best corrected visual acuity 0.7).
unchanged in 10 eyes (71%), and in these AMD eyes, the median decimal VA was 0.30 before treatment (range 0.08–1.0) and 0.2 at 3 months after treatment (range 0.05–0.7). Complications such as intraocular pressure elevation, infection, or cataract progression were not noted in any eyes.

### Comment

This interventional case series shows that trans-Tenon’s retrobulbar infusion of triamcinolone acetonide resulted in reduced fibrosis in the majority of eyes with small CNV, efficacy being best for idiopathic CNV or CNV related to PIC. The mechanism of action of triamcinolone acetonide in inhibiting CNV growth probably involves several pathways. The effect of corticosteroids in inhibiting inflammatory cells that participate in the neovascular response probably has a prominent role. Triamcinolone acetonide has been shown to inhibit basic fibroblast growth factor induced migration and tube formation of choroidal microvascular endothelial cells. Furthermore, triamcinolone acetonide inhibits choroidal neovascularisation induced by laser trauma in a rat model. Finally, triamcinolone acetonide may decrease vascular permeability, thereby decreasing influx of serum proteins that may contribute to an angiogenic microenvironment. Longer follow up and greater numbers of cases in a randomised clinical trial are needed to confirm these results.

### Retinoblastoma in a child conceived by in vitro fertilisation

As the number of infants born through in vitro fertilisation (IVF) grows, there is increased interest regarding the long term effects of IVF and other assisted reproduction techniques on such offspring. Recent reports have noted cancer in children born after IVF or fertility drug use (table 1). In 2001, retinoblastoma was reported to occur in a child born through IVF in Israel. Since then, an additional report documented four cases from the Netherlands. Here we add a sixth case and the first from the United States. Of these children four had unilateral retinoblastoma and two bilateral disease (table 2).

During 2002, a 16 month old child was referred to The New York Eye Cancer Center with no known family history of eye disease. She had a blind painful right eye with neovascular glaucoma. Intraocular pressures were 35 mm Hg in the right eye, and 14 in the left. Examination of the anterior chamber of the right eye revealed cells on the corneal endothelium and iris neovascularisation. While ophthalmoscopic examination of the right eye was not possible because of opaque media, ultrasonography revealed a densely calcified mass in the posterior pole (fig 1). Computed radiographic tomography demonstrated tumour calcification with no evidence of extracocular spread or retinal detachment. Post-mortem histopathology confirmed the diagnosis of retinoblastoma. The parents did not approve genetic studies of the child.

Further history revealed that this child was born through IVF with a donor egg and the father’s sperm. In order to carry the child, the postmenopausal mother received oestrogen and progesterone before and during gestation.

### Comment

Several theories of IVF related carcinogenesis exist. Prenatal exposure to fertility drugs may initiate cancer in the embryo or parental germ cells. However, an evidence based association between IVF treatments and cancer development (in the women taking the drugs) has not been established. Another possible mechanism has been associated with the culture medium used in the IVF test tube. Experiments on mice suggest that subtle changes in the ingredients of the culture media may alter the activity of imprinted genes. Like fertility drugs, it remains to be seen whether altered gene imprinting can lead to cancers such as retinoblastoma.

A third possible mechanism of carcinogenesis includes inheritance of genetic defects from gametes and embryo trauma performed during routine intracytoplasmic sperm injection (ICSI) type IVF. The most likely explanation for an increased risk of secondary carcinogenesis is that the population of patients seeking IVF is dissimilar to the general population. Patients seeking IVF are older or have medical problems that interfere with fertility. This poses a problem with any study other than a randomised prospective trial that compares babies from untreated infertility patients who become pregnant versus babies from infertile patients who become pregnant using IVF. To date all studies published are observations of clusters of disease with the suggestion that there is a cause and effect relation.

NR, not reported; AI, artificial insemination; ICSI, intracytoplasmic sperm injection.
Retinoblastoma is the most common intraocular cancer of childhood and affects approximately 300 children each year in the United States. Retinoblastoma is a manifestation of a de novo deletion or mutation of the q14 band of chromosome 13, occurring as a “second hit” during embryogenesis or the result of two hit deletions in retinal cells. In that it could be the result of chromosomal breakage and deletions in IVF born children, surveillance of retinoblastoma incidence in children born through IVF is warranted.

With the advent of assisted reproductive technology (ART) in 1977, American couples have increasingly turned to such treatments to overcome fertility problems. Nationwide, 99,629 procedures were performed in 2000 by ART. In that year, fertility treatments in which the egg and sperm are handled in the laboratory resulted in 25,228 live births and 35,025 infants. This report expands information on geography and determinants of both ART success and multiple birth risks (beyond 1099). Therefore, it seems reasonable to maintain a registry of post-IVF children, to support large surveillance of retinoblastoma incidence in children born through IVF.

Infantile angle closure glaucoma (ACG) is a rare consequence of retinopathy of prematurity (ROP) and usually occurs a few years after laser treatment for ROP.

A Medline search for ACG following laser photocoagulation extracted only one case. In the case, ACG occurred in 2 weeks after laser photocoagulation and although occurrence of iris bombe in both eyes was described, the mechanism for the ACG was not fully clarified. We present a case of bilateral ACG that occurred within a several weeks after the laser photocoagulation for ROP. We shall discuss the importance of ultrasound biomicroscopy (UBM) in the diagnosis.

**References**

**Case report**

A baby girl, born at 25 weeks gestation weighing 796 g, was diagnosed with stage 2 plus, zone 2 ROP bilaterally at 33 weeks. Diode laser photocoagulation, 986 applications right eye and 629 left eye, with 200-240 mW, 0.4 second duration, was performed by a paediatric ophthalmologist. On the following day, severe hyphaema was observed bilaterally but there was no evidence of choroidal detachment by B-mode ultrasound sonography. Topical atropine and corticosteroid were started and she was asymptomatic.
of the lens was also attached to the corneal endothelium (fig 2). Choroidal detachment and a retrolental mass were not observed by B-mode ultrasound sonography (fig 2).

Peripheral iridectomy was performed bilaterally (fig 1). Postoperatively, her peripheral anterior chamber deepened bilaterally although the lens in the right eye was still adherent to the corneal endothelium. Indirect ophthalmoscopy revealed normal cup to disc ratio. The IOP fell to normal levels bilaterally.

Comment

Shallow anterior chambers in ROP patients are known to be caused by various factors—for example, choroidal detachment after excessive photocoagulation, development of retrolental mass, or relative increment in lens thickness, but usually the cause of shallow anterior chamber cannot be determined. In our case, the development of hyphaema after photocoagulation induced posterior synechia, and the iris bombe followed. The displacement of the anterior chamber structures was induced by the forward movement of the iris lens diaphragm in the right eye, and the ocular fragility in premature baby may explain this deformity.

Vitreous haemorrhage is known to occur in 7.9% of ROP cases after photocoagulation. In our case, there is a possibility that the hyphaema was derived from vitreous haemorrhage. Another possibility is an accidental photocoagulation of persistent pupillary membranes and/or iridocorneal vessels caused the hyphaema. We are not aware of such morphological changes after photocoagulation for ROP. ACG that occurs immediately after retinal photocoagulation in ROP patients is rare, but is still an important complication. In ROP patients, the lens and its ligament are weak, and therefore not only ACG but also lens displacement occurred. It is important that we be aware of the possible development of ACG following retinal photocoagulation for ROP.

Treatment for central retinal vein occlusion (CRVO) remains disappointing despite recently proposed intraocular surgical techniques. We previously introduced the use of intravitreal tissue plasminogen activator (TPA) for acute central retinal vein occlusion in 1999. Numerous investigators have confirmed its safety and suggested that it may have a beneficial role in the treatment of acute central retinal vein occlusion.

Sequential treatment of central retinal vein occlusion with intravitreal tissue plasminogen activator and intravitreal triamcinolone

Treatment for central retinal vein occlusion (CRVO) remains disappointing despite recently proposed intraocular surgical techniques. We previously introduced the use of intravitreal tissue plasminogen activator (TPA) for acute central retinal vein occlusion in 1999. Numerous investigators have confirmed its safety and suggested that it may have a beneficial role in the treatment of acute central retinal vein occlusion.

Although some studies in rabbits suggest the rabbit retina is not permeable to TPA, followed up conservatively. During the follow up period, total posterior synechia was formed in the both eyes and the anterior chamber became shallow.

At 39 weeks, the corneal diameter had increased, and the anterior chamber was extremely shallow bilaterally. The intraocular pressure (IOP) in the right eye was elevated to 28 mm Hg, and she was referred to our hospital.

Our examination showed that the corneal diameter was increased to 11 mm bilaterally. Slit lamp examination showed corneal oedema and shallow anterior chamber depth bilaterally, especially in the right eye. The corneal oedema made the funduscopy difficult bilaterally. The IOP under the general anaesthesia was 33 mm Hg right eye and 17 mm Hg left eye. Persistent pupillary membranes and iridohyaloid vessels were observed but rubecosis iridis was not observed (fig 1).

Figure 2 Composite images of the anterior segment scanned with UBM (top) and schematic representations (bottom). (A) Left eye. Posterior synechia and iris bombe can be seen. C, cornea; L, lens; AC, anterior chamber; S, posterior synechia; PC, posterior chamber. (B) Right eye. The high echo lines (arrowheads) along the corneal endothelium represent the iris adherent to the corneal endothelium and the iris bombe. The lens is displaced into the anterior chamber and the anterior chamber is completely obliterated. The arrow represents the posterior capsule of the lens. Note that the cornea is distended and is thin as a result of the high intraocular pressure. The thickness of the cornea at the centre is 394 μm, and 613 μm in the left eye as measured with a caliper installed in the UBM model 840 Humphrey.

Figure 1 (A) Fundus photograph shows an acute CRVO with dilated retinal veins, retinal haemorrhages, and retinal oedema. (B) Fundus appearance 1 month after intravitreal injection of tissue plasminogen activator. (C) Photograph of the same eye 5 months later.
investigators found the porcine retina was, in fact, permeable to TPA.11 Our clinical experience with intravitreal TPA in humans with CRVO and large submacular haemorrhages strongly suggests that intravitreal TPA does cross the human retina. Greenberg et al12 were the first to report the possible beneficial effect of intravitreal steroids on patients with chronic CRVO.13 This report describes a sequential treatment strategy for patients with CRVO who present early in the course of their disease and can be performed in the office while avoiding the risks of vitrectomy. It utilises intravitreal TPA in the acute phase of the vein occlusion to attempt clot lysis, and then treats any remaining vascular leakage with intravitreal triamcinolone.

Case report
A 59 year old obese, hypertensive flight instructor presented with a sudden decrease in vision for 7 days in the right eye. Vision was 20/400 right eye and 20/20 left eye. The patient was diagnosed with an acute CRVO in the right eye (fig 1A). The left eye was normal. After being advised of the risks and benefits, the patient elected to undergo intravitreal injection of TPA (75 μg). Thirteen days later, the patient noted marked improvement in vision with 20/60 vision. Thirty four days after the injection, the vision had returned to normal and OCT showed decreased foveal thickness from 331 μm to 291 μm. The patient reported a significant improvement in vision with decreased metamorphopsia. Vision was 20/25 with no late leakage on the fluorescein angiogram (fig 2B).

Comment
To our knowledge, this represents the first published case of CRVO treated sequentially with intravitreal TPA for the acute phase and intravitreal triamcinolone for the chronic phase. TPA is a drug that must be used early in the course of thrombus formation to be effective. We do not recommend its use for patients with chronic symptoms. Intravitreal steroids appear to decrease the blood-retinal barrier breakdown and macular oedema, but recurrent oedema may occur since the steroids do not appear to affect the thrombus itself.

Severe post-laser suprachoroidal haemorrhaging in a diabetic patient receiving anticoagulants
Although the aetiology is not well understood, exsudative suprachoroidal haemorrhaging (ESH) is the most severe complication associated with intraocular surgery. Anticoagulants are considered a risk factor for spontaneous suprachoroidal haemorrhaging in cases with high myopia, age related macular degeneration, and diabetic retinopathy.10 However, ESH post photoocoagulation is extremely rare regardless of anticoagulant therapy. We have experienced a severe case of post-laser ESH correlated with anticoagulant therapy, which resulted in irreversible visual disturbance.

Case report
A 70 year old woman was diagnosed with pre-proliferative diabetic retinopathy based on fluorescein angiographic examinations. Two months before diagnosis, she had right eye cataract surgery. After the past 6 years, the patient received warfarin (4 mg/day) and aspirin (81 mg/day) because of atrial fibrillation after myocardial infarction. Laser photoocoagulation was performed in her right eye with a Nidek MC-7000, yellow-green laser. Operating conditions were 200–280 burns per session with a spot size 200 μm, exposure 0.2 seconds, power 100–120 mW using a Quadraspheric contact lens (Yolk, Tokyo, Japan). Treatment was separated into three partitions with a minimum 2 week interval between sessions. Three days after final photoocoagulation, the patient had a sudden visual loss to hand movements in slit lamp examinations, the retina seemed to be attached to the posterior surface of the implanted intraocular lens. Severe choroidal detachment was found by fundus examination (fig 1). The B-mode ultrasonography showed massive haemorrhaging in the choroidal space (fig 2). In systemic examinations, multiple purple spots were observed in both her arms. Microhaematuria was also found. Blood examination revealed blood sugar 167 mg/dl; platelet number 179 000 ×109/l; PT% 19% (control 70–120); PTs 28.7 seconds; APTT 80.2 seconds; PT INR 4.72 (control 1); APTT 80.2 seconds; PT INR 20.0–38.0; and bleeding time 5 minutes. Although surgery was planned to proceed as soon as the anticoagulant was washed out, her right eye lost all light perception before treatment.

Comment
We have described a case of ESH after laser photoocoagulation in a patient receiving anticoagulant therapy. Laser photoocoagulation is known as an effective treatment for various ocular diseases and is a widely used, non-incision surgical procedure. However, a number of complications have been reported, with some citing an irreversible visual disturbance.6 On the other hand, anticoagulant therapy is prevalent after cardiac/brain infarctions, which necessitate long term coagulation system management. In the present case, the PT INR was extremely prolonged (a respected value of 2–3 is...
appropriate for post-cardiac infarction). Presumably, choroidal microbleeding initiated by photoocoagulation persisted because of an overly suppressed coagulation system; blood pooled in the choroidal space, which assumed an ESH. To our knowledge, there is only one other similar case reported which assumed an ESH. To our knowledge, our system; blood pooled in the choroidal space, initiated by photocoagulation persisted.

Presumably, choroidal microbleeding initiated by photoocoagulation persisted because of an overly suppressed coagulation system; blood pooled in the choroidal space, which assumed an ESH. To our knowledge, there is only one other similar case reported which assumed an ESH. To our knowledge, our system; blood pooled in the choroidal space, initiated by photocoagulation persisted.
regimens with reported efficacy including a 6 month regimen of rifampicin (with streptomycin also given in the initial phase only) for pulmonary tuberculosis. Furthermore, the WHO recommendations are for active extra-pulmonary tuberculosis that has been diagnosed by specimen examination or strong clinical evidence, and give no recommendations for latent infection. As we have previously reported in a series on intraocular tuberculosis, systemic examination failed to identify a focus of active tuberculosis in the majority of our patients, and we have come to suspect that the uveitis we observed may be an immune response to latent tuberculosis antigen sequestered elsewhere. Therefore, the patients we described were given a diagnosis of “presumed intraocular tuberculosis,” that is, with uveitis presumed to be related to the Mycobacterium tuberculosis organism. Furthermore, we would like to clarify that in the cases of presumed ocular tuberculosis that received trans-Tenon’s retrobulbar triamcinolone infusion, this treatment was judged to be effective in two of three eyes. Regarding, since the focus of active or latent tuberculosis was never identified in our patients, a two drug regimen of isoniazid and rifampicin was used as a therapeutic trial for antituberculosis therapy. A similar therapeutic trial for ocular tuberculosis, albeit with isoniazid alone, has been previously advocated in Japan by Ishihara and Ohno.

With regard to the second comment, among the 16 patients who were receiving some form of systemic immunosuppressive therapy, we did not notice any difference in outcome when compared to patients who were not on immunosuppressive therapy. In other words, the efficacy of trans-Tenon’s retrobulbar triamcinolone infusion was the same. However, we suspect that the recurrence rate after triamcinolone infusion may be different, and we are currently investigating this possibility.

Low vision care
The latest issue of Community Eye Health (No 49) deals with the problems and management of low vision. For further information please contact: Journal of Community Eye Health, International Resource Centre, International Centre for Eye Health, Department of Infectious and Tropical Diseases, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT, UK (tel: +44 (0)20 7612 7964; email: Anita.Shah@lshim.ac.uk; online edition: www.jech.co.uk). Annual subscription (4 issues) UK £28/US$45. Free to developing country applicants.

Elimination of avoidable blindness
The 56th World Health Assembly (WHA) considered the report on the elimination of avoidable blindness (doc A56/26) and urged Member States to: (1) Commit themselves to supporting the Global Initiative for the Elimination of Avoidable Blindness by setting up a national Vision 2020 plan by 2005; (2) Establish a national coordinating committee for Vision 2020, or a national blindness prevention committee to help implement the plan; (3) Implement the plan by 2007; (4) Include effective monitoring and evaluation of the plan with the aim of showing a reduction in the magnitude of avoidable blindness by 2010; (5) To support the mobilisation of resources for eliminating avoidable blindness. The WHA also urged the Director-General to maintain and strengthen WHO’s collaboration with Member States and the partners of the Global Initiative for the Elimination of Avoidable Blindness as well as aid in the coordination and support of national capability.

4th International Congress on Autoimmunity
The 4th International Congress on Autoimmunity will take place 3-7 November 2004 in Budapest, Hungary. The deadline for the receipt of abstracts is 20 June 2004. Further details: Kences International Global Congress Organisers and Association Management Services, 17 Rue du Cendrier, PO Box 1726, CH-1211 Geneva 1, Switzerland (tel: +41 22 908 0488; fax: +41 22 732 2850; email: autoim04@kences.com; website: www.kences.com/autoim04).

XVI International Congress for Eye Research

Glaucocma Society Silver Jubilee Meeting 2004
The Silver Jubilee Meeting and Dinner for the Glaucocma Society will be held on 3 December 2004 at the Royal College of Physicians in Regents Park, London. The meeting will take place between 8.30am and 5pm and the dinner will be held between 6.30pm and 10pm. For further information, please contact: Janet Flowers, Administrator, 29 Quarry Hill, Grays, Essex, RM17 5BT (tel: 01375 383172; e-mail: glauscoc@ukiere.freeserve.co.uk).
