Sir,

Extrusion of sebaceous glands through the follicular canal onto the skin surface is a well known phenomenon first described by Pinkus and Mehrgan.¹ Transfollicular sebaceous gland extrusion is explained as an artifact caused by damage to the fragile sebaceous gland by the effects of the physico-chemical changes that occur during tissue processing and the squeezing effect of the microtome knife as it slices through the paraffin block containing the biopsy tissue, pushing up the dislodged sebaceous gland outward through the common folliculo-sebaceous conduit.

Some authors have expressed reservations about it being an artifact, proposing instead that it be considered a natural phenomenon.² Sebaceous glands are found either totally extruded onto the skin surface, or may be seen in a subcorneal location.

We report an unusual location of sebaceous gland extrusion, namely, within the suprabasal blister of pemphigus vulgaris.

A 34 year old male presented to one of us (HSM), with a one year history of multiple fluid filled blisters all over the body. He had earlier received short courses of oral steroids in the dose of about 15-20 mg prednisolone per day with partial clearing of the blisters. However, on discontinuing the steroids, he had developed extensive relapse with numerous small flaccid vesicles appearing on normal looking skin. Oral lesions had been present on and off, but no oral involvement was present at the time of this presentation. A clinical diagnosis of pemphigus was considered and a biopsy that included one of the new vesicles was obtained from the right side of the upper back.

Sections from the biopsy showed a small suprabasal blister with an intact sebaceous lobule occupying the cavity of the blister. (Figure 1) This structure was identified as a sebaceous lobule as it was made up of typical mature sebocytes with central scalloped nuclei and abundant vacuolated cytoplasm. A few acantholytic cells were seen in the blister, but no inflammation or other blisters were seen in the section. Serial sections taken through the block revealed in the mid dermis a folliculo-sebaceous structure that showed suprabasal clefts with acantholysis in follicular and sebaceous epithelium, findings consistent with pemphigus vulgaris.

In sum, we report an unusual histopathological finding of extrusion of sebaceous gland into the blister cavity of pemphigus vulgaris. The acantholytic process in the...
lesion biopsied in our patient appears to affect the folliculo-sebaceous epithelium leading to sebaceous gland extrusion into an acantholytic suprabasal blister within the epidermis.

Dermatological findings in chronic alcoholics

Sir,
I read with great interest the recent article by Dr. G.S. Rao describing the changes in the skin, nails, hair and oral cavity.¹

The author’s efforts are commendable. However, I would like to make certain observations and draw attention to other dermatological manifestations in alcoholics not reported by the author. These include type I allergic skin manifestations, palmar plantar hyperhidrosis (PPH), spontaneous skin necrosis,² and increased risk of basal cell carcinoma (BCC). Allergic skin manifestations in alcoholics occur due to a combination of a direct effect of alcohol and an indirect effect through elevation of IgE.³ Alcoholics are frequently noted to have PPH. As the findings of peripheral nerve conduction (sympathetic skin responses) studies do not differ between alcoholics with PPH and those with primary PPH, hyperhidrosis is believed to occur due to impaired central sweat control mechanisms.⁴ In a large prospective cohort study, the total alcohol and white wine intake were associated with a higher risk of occurrence of BCC in both men and women.⁵

In addition, chronic alcohol consumption affects the clinical presentation and treatment responsiveness of certain dermatological conditions. Excess alcohol consumption is associated with the onset and flare-up of psoriasis and discoid eczema.⁶ Alcoholism also leads to a poor response to anti-psoriatic treatment,⁷ and contributes to an excess mortality in patients with psoriasis.⁸

Response by the author

Sir,
I appreciate the keen interest shown by the reader in my article “Cutaneous changes in chronic alcoholics”. I thank the reader for sharing his knowledge about the topic. However, changes like spontaneous skin necrosis were not seen in our patients as none of them were in
