Role of physiotherapists in intensive care units of India: A multicenter survey

Jithendra A. Kumar, Arun G. Maiya*, Daphne Pereira*

Abstract

Purpose: The purpose of this study was to find what role physiotherapists play in the care of the critically ill in Indian Intensive Care Units (ICU). Materials and Methods: Study Design and Setting: Exploratory cross-sectional survey. Questionnaires were sent to 260 ICUs in India. A stamped self-addressed envelope was enclosed with the questionnaire and a period of six weeks for completion were given in an attempt to ensure good response rates. If response was not obtained within six weeks, two subsequent reminders were sent to the hospitals with a further time gap of six weeks. Results: Eighty-nine completed questionnaires were received and analyzed, representing 35% of the questionnaires sent. The present study revealed that, 24% of ICUs had a resident physiotherapist available during the night and 79% of physiotherapists available on-call. In almost 90% of ICUs physiotherapists performed chest manipulations, mobilization, incentive spirometry and postural drainage. Correlation of physiotherapists’ role between different states of India, were performed by Chi-square. Mann-Whitney U test was performed to compare, within each of the five states for two types of postings in relation to the years of experience in ICU. Conclusion: All physiotherapists in ICU are routinely involved in chest physiotherapy and mobilization.

Key words: Chest physiotherapy, Indian intensive care unit, multicenter survey, physiotherapy

Introduction

“An intensive care unit (ICU) is a specially staffed and equipped hospital ward dedicated to the management of patients with life-threatening illnesses, injuries or complications” (Oh, 1998).[1] Throughout the course of ICU development, the role and responsibility of the physiotherapist has been poorly defined. In an ICU consensus conference in 1983, authors clarified the roles of physicians and nurses but not physiotherapists. In regard to physiotherapists it was simply mentioned that they should be included in the ICU team and should be involved in any continuous training programs. Consequently, there is little uniformity in physiotherapy training or duties, with considerable variation between and sometimes within countries.[2] Although a wide variety of literature is available about the roles of nurses and physicians in the ICU, the role of physiotherapists has received comparatively little attention and remains largely undefined and variable across sites.[3,4]

Physiotherapists in the ICU are part of a multidisciplinary team involved in the treatment of critically ill patients. Physiotherapists liaise closely with medical, nursing and other allied health professionals regarding patient condition, progression and treatment plans.[5]

In order to understand the role of physiotherapists, two things must be considered, namely the degree to
which specialist physiotherapy services are available in the ICU and the specific tasks that are performed by physiotherapists in the ICU. Literature regarding the staffing levels and the availability of physiotherapists in the ICU is rare.

In a study of European ICUs, Norrenberg and Vincent[6] found that one quarter of the ICUs did not have exclusive physiotherapists for ICUs and two thirds had no physiotherapist available after hours, suggesting that the inclusion of physiotherapy within the ICU multidisciplinary team may not be firmly established.

The precise role that physiotherapists play in the ICU varies considerably from one unit to the next, depending on factors such as the country in which the ICU is located, local tradition, staffing levels, training and expertise.[7] The referral process is one example of this variation, in some ICU’s, physiotherapists assess all patients, whereas in other ICU’s patients are seen only after referral from medical staff.[7] Despite the emphasis on multidisciplinary team, the lack of role definition has resulted in many specialist physiotherapy services being subsumed by other professional groups, mostly nursing staff. The lack of strong evidence base to support the role of physiotherapists in the ICU has undermined the importance of providing specialist physiotherapists.

In intensive care units, physiotherapists are involved in the prevention and treatment of pulmonary, circulatory, musculoskeletal system and integumentary complications, by regular chest physiotherapy, graded mobilization and proper positioning of patients. The role of physiotherapists as stated by Kathy Stiller,[8] in the ICU are positioning, mobilization, manual hyperinflation, percussion, vibration, coughing, suctioning, various breathing exercises and limb exercises. Colin F. Mackenzie[9] stated the role of physiotherapists in ICU as positioning, postural drainage, percussion, vibration, manual lung inflation, coughing, tracheal suctioning, breathing exercises, patient mobilization and application of aerosol, humidification, incentive spirometry, forced expiratory techniques, bronchodilators and mucolytic agents.

There is no available information on the role of physiotherapists in ICUs in India. The purpose of this study was to find what role physiotherapists play in the care of the critically ill in Indian ICU.

Materials and Methods

Study design
Exploratory cross sectional survey.

Participants
Physiotherapists who are currently working in ICU with two years of working experience were requested to fill the questionnaire.

Procedure
The study was reviewed and approved by the institutional ethical committee, Manipal College of Allied Health Sciences (MCOAHS), Manipal Academy of Higher Education (MAHE). The lists of hospitals were obtained from Indian Association of Physiotherapists (IAP) and Medical Council of India (MCI) websites. A total of 500 hospitals were identified. In India, both modern medicine and traditional systems of medical practice are well established. In this study the traditional systems of medical practices like Unani, Ayurveda, homeopathy and dental colleges were excluded and a total of 260 hospitals from the above mentioned websites were included in the study.

Survey was done by the questionnaire and pilot study was conducted at Kasturba Medical College Hospital, Manipal and Kasturba Medical College Hospital, Mangalore. Physiotherapists involved in ICU were given the questionnaire, experts in the field of cardio-respiratory physiotherapy with 10 years of working experience were consulted for their comments on the questionnaire design, structure and content and a final questionnaire was prepared. The questionnaire covers details of the hospital (number of beds in hospital and ICU beds), therapist profile (qualification, experience) and role of physiotherapists (chest manipulation, positioning, mobilization, breathing exercise, postural drainage and advanced physiotherapeutic techniques) in ICU and several other questions were incorporated to elicit the information about physiotherapists awareness to ICU.

Questionnaires were posted to the Head of the department of physiotherapy of the hospitals selected. As per the inclusion criteria, physiotherapists who are currently working in ICU with two years of working experience, were requested to fill the questionnaire.

A covering letter was included explaining the purpose of
the questionnaire, identifying the researcher and assuring confidentiality.

A stamped self-addressed envelope was included with the questionnaire and a period of six weeks for completion was given in an attempt to ensure good response rates. If response was not obtained within the stipulated time period, two subsequent reminders were sent to the hospitals with a time gap of six weeks for the first reminder and four weeks for the second reminder. Non-respondents were excluded from the study after the second reminder.

**Data analysis**

Questionnaire contents were statistically analyzed by SPSS (V. 10) software. Data was summarized using percentages. Chi-square was performed for correlations of physiotherapists' role between states, Mann-Whitney U test was performed to compare years of experience of physiotherapists in ICU with their postings in ICU, Kruskal-Wallis test was performed to compare physiotherapists' years of experience in ICU within different states.

**Results**

A total of 89 completed questionnaires were received out of 260 (35% response rate) with the largest response from Karnataka, Maharashatra, Andhra Pradesh, Delhi and Tamil Nadu in descending order [Table 1]. Out of 89 questionnaires received, 23 (26%) were from hospitals with more than 500 to 1000 beds. Forty (45%) respondents were from hospitals with 10 to 20 beds in ICU. Majority of the respondents (59%) working in ICU were postgraduate qualified physiotherapists [Table 2].

Twenty four percent of ICUs had a resident physiotherapist available during the night and 79% of physiotherapists available on call. Many respondents, 78%, reported their posting to be on rotation basis rather than on permanent basis.

The role of physiotherapists in ICUs is presented in [Figure 1]. Ninety one percent respondents reported to be involved in chest manipulation, 100% in mobilization, 100% in breathing exercises, 94% incentive spirometry, 98% in postural drainage, 95% in assisted coughing and huffing.

The respondents reported that (55%) of the referral system in the ICUs is by physician. Overall response rate of the physiotherapists being in setting ventilatory parameters was 10%, with respondents involved in weaning being 18%.
Correlation of role of physiotherapists between different states of India [Table 3] has been performed by Chi-Square, except ambulation of non-intubated patients, all other parameters were found to be non significant.

Mann-Whitney U test was performed to compare, within each of the five states for two types of postings in relation to the years of experience in ICU [Table 4] and it was found to be insignificant significant. Kruskal-Wallis test was performed to compare between five states for two types of postings with relation to the years of experience [Table 5] and was found to be insignificant.

### Discussion

Remarkably, a dearth of literature exists regarding the role of physiotherapists in intensive care units. In order to understand the role of physiotherapists, two things must be considered, namely the degree to which specialist physiotherapy services are available in the ICU, and the specific tasks that are performed by physiotherapists in the ICU. Literature regarding the staffing levels and availability of physiotherapists in the ICU is rare.

According to the results of our survey, Indian ICU physiotherapists perform both the roles of chest physiotherapy and mobilization. Apart from the roles mentioned in the questionnaire, therapists are also involved in application of non-invasive ventilation, proprioceptive neuromuscular facilitation in respiration, bedsore management, active cycle of breathing techniques and autogenic drainage.

In our study 91% of the respondents reported to perform chest manipulation (percussion, vibration, suctioning), on comparison with other countries Australian physiotherapists (79%), European (98%) counterparts.

Therapists in ICU are not only involved in chest physiotherapy techniques, but also reported to have a very active role in mobilization and positioning. Mobilization from our study was found to be 100%, which is on par with Australia (100%) and Europe (100%).

The above data reveals that therapists from different parts of the country are involved in patient mobilization inside the ICU which focuses on representing early rehabilitation. In, therapeutic positioning was found to be 75%, while it was higher in Australia (100%) and Europe (90%).

We found on-call physiotherapists available in Indian ICUs were 79% as compared to elsewhere, Europe (83%), Australia (66%) and South Africa (96%).

Even though recognition of the need for physiotherapists in ICU is growing world wide, the kind of referral system being practiced in Indian ICUs is physician-based (55%) rather than being standard treatment. Physiotherapists

No conclusion could be made between duration of experience of physiotherapists in ICU with postings in ICU and duration of experience with different states.

Future studies should be aimed at identifying probable factors influencing the role of physiotherapists in ICU-like hospital administration policies, inter-professional needs and type of specialized care required.

More number of ICUs should be included in the future studies.

### Conclusions

1. Our study showed that not all patients in Indian ICUs get routine chest physiotherapy as part of their ICU care unless referred by an ICU physician, so physiotherapy should be standard routine management of such patients.

2. All physiotherapists in the ICU are routinely involved in both chest physiotherapy and mobilization.
