Indian Journal of Medical Sciences

ISSN 0019-5359

Indian Journal of Medical Sciences is a monthly journal published as a medium for the advancement of scientific knowledge in all the branches of Medicine and allied Sciences and publication of scientific investigation in these fields. It is also intended to present this as a form suitable to the general practitioner and primary care physician.

The journal is owned by the Indian Journal of Medical Sciences Trust, a registered charitable organisation and published by Medknow Publications, Mumbai, India.

All the rights are reserved. Apart from any fair dealing for the purposes of research or private study, or criticism or review, no part of the publication can be reproduced, stored, or transmitted, in any form or by any means, without the prior permission of the Editor, Indian Journal of Medical Sciences.

The information and opinions presented in the Journal reflect the views of the authors and not of the Indian Journal of Medical Sciences Trust or the Editorial Board. Publication does not constitute endorsement by the journal.

Indian Journal of Medical Sciences and/or its publisher cannot be held responsible for errors or for any consequences arising from the use of the information contained in this journal. The appearance of advertising or product information in the various sections in the journal does not constitute an endorsement or approval by the journal and/or its publisher of the quality or value of the said product or of claims made for it by its manufacturer.
Sir,

A 20-year-old female showed a comatose state for 3 days. Previously she had been treated for falciparum malaria with parenteral quinine 1 gm loading dose followed by 500 mg thrice a day for 8 days. On the sixth day, she developed altered consciousness. On arrival, the temperature was 38°C, pulse 126/min, respiratory rate 24/min and blood pressure 120/70 mmHg. Chest, cardiovascular system and the abdomen were normal. Neurological examination disclosed coma, decerebration, hypertonia, hyperreflexia and Babinski’s responses. Laboratory tests showed anemia (6.7 gm%), and the serum biochemistry was normal. The peripheral blood smear examination suggested postmalarial infection. On cerebrospinal fluid examination, no malarial parasites were seen. Cerebrospinal fluid examination, 100 lymphocytes/μl; proteins 45 mg/dl; and glucose level 84 mg/dl. MRI of the brain showed diffuse white matter hyper-intensities on T2 images, involving the subcortical white matter, corpus callosum and midbrain. Treatment with empirical broad-spectrum antibiotic was started (intravenous Cefepime 2 g BD with Teicoplanin 300 mg BD), and 2 units of blood were transfused. She remained deeply comatose and febrile; and after the MRI scan, intravenous methylprednisolone 1 g per day was administered for 3 days. The fever subsided and the patient showed a marked neurological improvement. Postmalarial neurological syndrome is defined by an acute onset of neurological abnormalities in patients recently recovered from severe Plasmodium falciparum malaria. The lack of malarial parasites on peripheral blood smear examination distinguishes postmalarial neurological syndrome from cerebral malaria.

Acute disseminated encephalomyelitis is an acute demyelinating disease occurring 1-3 weeks after a viral infection or vaccination.[1,2] The illness of our patient began after severe falciparum malaria complicated by a rapidly oncoming demyelinating illness after anti-malarial therapy. To the best of our knowledge, there are only three cases of ADEM following falciparum malaria.[3] The second case had neurological disturbances and multiple high-intensity lesions in the brain after recovery from Plasmodium falciparum malaria.[3] The third case presented with an ADEM-like illness after treatment of falciparum malaria. Identification of Varicella-Zoster virus infection using polymerase chain reaction on cerebrospinal fluid suggested infection.[4] The neurological syndrome in our patient occurred after anti-malarial therapy and responded to corticosteroids. MRI abnormalities reported in cerebral malaria include cortical infarcts or focal or diffuse white matter hyper-intensities. In ADEM, MRI shows diffuse T2 hyper-intensities involving the subcortical white matter, corpus callosum and brain stem.[5] MRI findings in our patient were suggestive of ADEM.

Acute disseminated encephalomyelitis can be regarded as a neurological complication of severe falciparum malaria. Raised levels of neurotoxic cytokines in the cerebrospinal fluid, tumor necrosis factor-α and interleukins 2 and 6 have been seen in patients with severe malaria and PMNS.[6] The latency to neurological involvement after eradication of the parasite and the response to steroid treatment in our patient support an immunological mechanism.
