Abstract: DNA barcoding is helping in discovering high levels of cryptic species and an underestimation of biodiversity in many groups of organisms. Although mammals are arguably the most studied and one of the least speciose taxonomic classes, the rate of species discovery is increasing and biased for small mammals on islands. An earlier study found bats in the Caribbean as a taxonomic and geographic deficiency in the International Barcode of Life initiative to establish a genetic reference database to enable specimen identification to species. Recent surveys in Dominican Republic, Jamaica, and Martinique have documented and barcoded half of the 58 bat species known from the Caribbean. I analyze all available barcode data of Caribbean bats to investigate biogeography and cryptic species in the Neotropical region. Analysis of the mitochondrial DNA gene cytochrome c oxidase subunit 1 results in a phylogenetic tree with all but one species as well-supported and reciprocally monophyletic. With a broader sampling across the Neotropics, there are also divergent lineages that exhibit biogeographic structuring: (1) phylogenetic split between northern and southern Dominican Republic in 3 species, (2) 2 taxa with cryptic species associated with higher degree of island endemism, (3) populations of 2 widely distributed species with deep divergence between the Caribbean and North and Central America, and (4) 1 species in the Caribbean with affinities to taxa in South America.

Keywords: Antilles, Chiroptera, Dominican Republic, Jamaica, Martinique.

Introduction

Surprisingly for a well-known and studied group of animals, about 300 new species of mammals have been described in the last decade (Reeder et al. 2007). Furthermore, the rate of discovery is biased to smaller mammals on islands, although most of this has been documented in the Old World tropics. One of the primary factors is the increased use of molecular methods, in particular DNA sequencing, that is uncovering cryptic species in many widely distributed but morphologically similar taxa (Baker and Bradley 2006). DNA barcoding of the cytochrome c oxidase subunit 1 (COI) gene for specimen identification and species discovery (Hebert et al. 2003) is at the forefront. For example, a recent study on bats in Southeast Asia estimated a 50% increase in undiscovered species diversity (Francis et al. 2010). By contrast, the Caribbean was noted as a region of the world that was lacking in DNA barcodes of mammals (Lim 2012), contributing to a bias towards new species descriptions from the Paleotropics (Reeder et al. 2007). The majority (79%) of the 73 species of extant terrestrial mammals in the Caribbean are bats, of which 69% are endemic (Dávalos and Turvey 2012). Moreover, 42% of the bat species endemic to the Caribbean are threatened (www.iucnredlist.org). There is an urgent need to document the species diversity in this conservation hotspot, ranked number three in terms of regions in the world with high endemism coupled with high habitat loss and small area (Myers et al. 2000).

The purpose of this study is to summarize DNA barcodes to ascertain the genetic diversity of bats from the Caribbean and compare barcode clusters to currently recognized species. In addition, a more detailed assessment with a broader taxonomic survey of closely related taxa and a wider geographic sampling of continental populations will examine phylogenetic structuring within species and implications for the biogeography of bats in the

Neotropics. This study complements earlier work on the phylogeny and biogeography of Caribbean bats by Dávalos (2005, 2006, 2007), but with increased geographic sampling on several islands in the Greater Antilles based on recent fieldwork in Jamaica (Lim and Arcila Hernandez 2016) and Dominican Republic (Lim et al. in press) and in the Lesser Antilles based on recently deposited sequences in Genbank (<http://www.ncbi.nlm.nih.gov/genbank>) from Martinique.

Materials and methods

DNA barcodes of 29 of the 37 recognized species from Jamaica, Dominican Republic, and Martinique were analyzed in this study, which represents half of the 58 known extant species of bats in the Caribbean (Dávalos and Turvey 2012). This diversity was represented by 246 samples (Table 1), including 81 samples of 10 species from Jamaica as reported by Lim and Arcila Hernandez (2016), 132 samples of 15 species from Dominican Republic as reported by Lim et al. (in press), and 33 samples of 10 species from Martinique deposited on GenBank. The 8 species not included in the study were *Ariteus flavescens*, *Eumops auripendulus*, *Eumops glaucinus*, *Lasiurus degelidus*, *Natalus jamaicensis*, *Natalus stramineus*, *Nyctinomops macrotis*, and *Phyllonycteris aphylla*.

Molecular methods followed the DNA barcoding procedure for bats as outlined by Clare et al. (2007). In summary, DNA was isolated using a Phenol/Chloroform extraction procedure with approximately 1 mm³ of tissue (muscle or liver) and an elution volume of 60 ul. Bidirectional primers used for recovering the COI mtDNA gene were VF1 (5'-TTCTCAACCAACCACAAAGACATTGG-3') and VR1 (5'-

TAGACTTCTGGGTGGCCAAAGAATCA-3'). The polymerase chain reaction (PCR) consisted of 8.92 ul H₂O, 1.25 ul EH Buffer, 0.5 ul or 10 uM of each primer, 0.28 ul or 10 mM dNTP's (Invitrogen), 0.05 ul taq (Invitrogen), and 1 ul DNA. Amplification conditions were 94C for 2 min; then 36 cycles of 94C for 30 sec, 50C for 30 sec, and 72C for 1 min 30 sec; followed by 72C for 3 min; and then a 4C hold. The PCR product was separated on a 1% agarose gel at 100 V for 20 min. The PCR band was excised and placed in a spin column made by cutting the ends of 200-ul filter tips that were placed in 1.5-ml microcentrifuge tubes. These were spun at full speed for 10 min, and 4 ul of this product was used in a sequencing mix of 3 ul H₂O, 2 ul 5x sequencing buffer, 0.5 ul primer, and 0.5ul BigDye. The sequencing reactions and precipitation followed the protocol of Applied Biosystems and were then resuspended in 10ul HiDi formamide and placed on the sequencer. Resultant chromatograms were edited using BioEdit and a single contig created for each specimen.

Sequence alignment was done with Sequencher version 4.8 (Gene Code Corp. 2007), and no internal stop codons were present to indicate pseudo-genes. Genetic distances were calculated using the Kimura 2-parameter model of nucleotide substitutions with pairwise deletion in MEGA6 (Tamura et al. 2013), which is appropriate for closely related taxa (Nei and Kumar 2000) and enables comparison to the similarly mutating mitochondrial cytochrome b gene used by Baker and Bradley (2006) in the genetic species concept for mammals.

Phylogenetic trees were constructed using the neighbour-joining distance method, as a quick algorithm for calculating large phylogenies (Kumar and Gadagkar 2000), and maximum likelihood with pairwise deletion and nearest neighbor interchange based on the best-fit nucleotide substitution model with the lowest Bayesian Information Criterion as implemented in MEGA6. Topological support in all trees was tested with 500 bootstrap replicates. Trees were

constructed first for the 246 samples from the Caribbean and then separately for species groups exhibiting phylogenetic structuring, with comparative sequences of closely related taxa downloaded from GenBank (Table S1).

Results

DNA barcode variation of 29 Caribbean bat species, as summarized by maximum likelihood (based on a general time reversible substitution model with gamma distribution and some invariable sites) and neighbor-joining trees, recovered well-supported ($\geq 95\%$) monophyletic clades for all but 1 species (Fig. 1). The exception was *Brachyphylla pumila*, which was paraphyletic in relation to *B. cavernarum*. Of the 5 intragenera groupings, all have high bootstrap values ($\geq 90\%$) except *Pteronotus* ($\geq 66\%$). Several intergeneric relationships are well-supported ($\geq 95\%$) including (*Phyllonycteris*, *Erophylla*) and ((*Ardops*, *Phyllops*, (*Artibeus*)). All other higher-level relationships were poorly supported, and there were no natural groupings at the taxonomic level of family. This is not unexpected because the rate of nucleotide substitution of COI typically has phylogenetic signal at the species level, and its appropriateness decreases at higher levels (Hajibabaei et al., 2007).

Kimura 2-parameter interspecific sequence divergence averaged from 33.6% between *Erophylla sezekorni* and *Lasiurus minor* to 1.2% between *Brachyphylla pumila* and *B. cavernarum* (Table 2). Average intraspecific divergence ranged from 4.7% for *Macrotus waterhousii* to no variation within 8 species. Two species (*Natalus major* and *Erophylla sezekorni*) were represented by only 1 sample.

For broader studies of taxonomic groups across the Neotropics, maximum likelihood tree based on Tamura 3-parameter substitution model with some invariable sites recovered 2 species with deep phylogenetic splits between populations from the Caribbean and Central and North America (Fig. 2). Samples of *Eptesicus fuscus* from the Dominican Republic have an average sequence divergence of 8% from those collected from Canada and the United States. Similarly, populations of *Tadarida brasiliensis* from Martinique are 6% divergent from Guatemala, Mexico, and United States.

Based on a maximum likelihood analysis with a Tamura 3-parameter substitution model with gamma distribution and some invariable sites, one species has a closer affinity to South America. Although poorly supported, *Myotis martiniquensis* from Martinique is embedded within a clade of primarily South American occurring taxa (Fig. 2). It has an average sequence divergence of 6.7% from its poorly supported sister clade of *M. riparius*.

A maximum likelihood tree based on Hasegawa-Kinoshita-Yano substitution model with gamma distribution for three Caribbean endemic genera with COI sequences from more than one island exhibit contrasting levels of genetic distance and taxonomic rank (Fig. 3). *Brachyphylla pumila* from Dominican Republic is not reciprocally monophyletic with respect to *B. cavernarum* from Martinique, and there is an average sequence divergence of 1.2%. *Erophylla bombifrons* from Dominican Republic is the sister species of *E. sezekorni* from Jamaica, and the average sequence divergence is 4.3%. By contrast, the average sequence divergence between populations of *Monophyllus redmani* from Dominican Republic and Jamaica is 8.1%. The average sequence divergence between the sister species *M. redmani* and *M. plethodon* from Martinique is 14%.

Based on a maximum likelihood analysis with a best fit Hasegawa-Kinoshita-Yano substitution model with some invariable sites, there is one widely distributed bat genus that also has phylogeographic patterns associated with individual Greater Antillean islands. Populations of *Molossus molossus* from Jamaica and Dominican Republic are divergent from each other and other continental populations by about 4% (Fig 3) as reported recently by Lim et al. (in press).

Based upon maximum likelihood analyses using the Hasegawa-Kinoshita-Yano substitution model with gamma distribution for *Macrotus* and Tamura 3-parameter model with some invariable sites for *Pteronotus*, there is a phylogenetic break between northern and southern Dominican Republic. Pairwise sequence divergence averaged 7.6% between populations of *Macrotus waterhousii*, 3.4% in *Pteronotus pusillus*, and 1.3% in *P. quadridens* (Fig.4 6) as documented in an earlier study (Lim et al. in press).

Discussion

Phylogenetic relationships of Caribbean bats based on the mitochondrial gene COI identified 4 general biogeographic patterns when compared to a wider sampling across the Neotropics. However, typical systematic reviews over the years have focused primarily at the taxonomic rank of family or below. In combination with different researchers and classifications, this has resulted in an uneven treatment at the species level. A broader study within bats of the Caribbean gives an opportunity to standardize and update the taxonomy with the benefit of applying molecular methods such as DNA barcoding to the suggestion that cryptic species are contributing to the increasing trend of discovering new species of mammals (Baker and Bradley 2006; Reeder et al., 2007).

Previous studies on the biogeography of bats in the Caribbean have taken a distributional occurrence (Baker and Genoways 1978) or ecological (Presley and Willig 2008) approach. Although there have been some recent studies on individual families (Dávalos 2005, 2006, 2007), a broad phylogenetic approach has not been done for the order Chiroptera, but Dávalos and Turvey (2012) outlined gaps in our knowledge that should be addressed. I present a preliminary overview of genetic diversity in the Caribbean and compare it to current taxonomy and the implications to biogeography of bats in the Neotropics.

Broad phylogeographic structuring is seen in 2 widely distributed species that occur in the Caribbean and primarily on the continental mainland of North America and into Central America. Although both *Eptesicus fuscus* and *Tadarida brasiliensis* are distributed in South America, they are not found east of Venezuela into the Amazon basin (Gardner 2008). Geographic sampling of DNA barcoding is abysmal for these 2 species, but average sequence divergence at COI is 6% between Caribbean and mainland populations, which is comparable to cytochrome b values for sister species of bats and suggestive of the cessation of gene flow (Baker and Bradley 2006). There are subspecies names applicable to these Caribbean populations: *Eptesicus fuscus hispaniolae* and *Tadarida brasiliensis antillarum*.

At shallower levels of divergence, there is also phylogeographic structuring linking Caribbean and Central American populations of *Glossophaga soricina* and *Artibeus jamaicensis*. There is a haplotype shared among individuals of *A. jamaicensis* from Dominican Republic, Jamaica, and the Yucatan Peninsula of Mexico, suggesting ongoing gene flow (Lim and Arcila Hernandez 2016). This result supports an earlier study of restriction site data with shared mtDNA genotypes between the Caribbean and Yucatan (Phillips et al. 1991). For *G. soricina*, the Jamaican population comprises a well-supported monophyletic clade that is nested within a

larger geographic clade that includes Central America and South America west of the Andes to the exclusion of populations from east of the Andes (Hoffman and Baker 2001; Lim and Arcila 2016).

However, there is 1 species occurring in the Caribbean that has affinities to South America. Although the deeper phylogenetic relationships are not well supported in the COI tree, *Myotis martiniquensis* is allied with species occurring primarily in South America, but *M. riparius* does extend into southern Central America (Gardner 2008). These 2 species have an average sequence divergence of 6.7%. Similar results were found using the cytochrome b gene (Larsen et al 2012), although the taxonomic data sets were not identical.

Three endemic Caribbean genera have varying degrees of sequence divergence associated with different islands. The allopatric sister species *Erophylla sezekorni* from Jamaica and *E. bombifrons* from Dominican Republic have an average sequence divergence of 4.3%. By contrast, populations of *Monophyllus redmani* from Jamaica and Dominican Republic are divergent by 8.1%. They are currently recognized as subspecies *M. r. redmani* and *M. r. clinephus*, respectively. The sister species is *M. plethodon*, which is distributed in the Lesser Antilles including Martinique, and divergent by 14%. In comparison, *Brachyphylla cavernarum* from Martinique has an average sequence divergence of 1.2% from *B. pumila* in the Dominican Republic and exhibits a weakly supported paraphyletic arrangement. However, *B. cavernarum* is larger with a forearm length averaging > 60 mm, and *B. pumila* is smaller but within the size range of *B. nana* from Cuba, which it was previously synonymized under (Swanepoel and Genoways 1978). More recently, *B. pumila* was recognized as a distinct species based on 23 fixed differences in cytochrome b from *B. nana* (Dávalos 2004). A systematic review is needed to resolve this taxonomic instability.

Two genera more broadly found throughout the Neotropics also exhibit deep divergence in DNA barcoding sequences associated with Caribbean islands (Lim et al. in press). Earlier molecular studies (Dávalos 2006), combined with recent analysis of echolocation call frequencies (de Thoisy et al. 2014), have identified several cryptic species within the widely distributed *Pteronotus parnellii*. The nominate species is now restricted to Jamaica, *P. pusillus* to Hispaniola, and *P. portoricensis* to Puerto Rico. Similarly, the broadly occurring *Molossus molossus* also needs to be separated into several species because of a polyphyletic relationship with respect to *M. rufus* and *M. coibensis* identified in earlier studies of COI variation in the Caribbean (Lim and Arcila Hernandez, 2016; Lim et al. in press). Available names include *M. milleri* for populations in Jamaica and *M. verrilli* in Hispaniola. Individuals from the Lesser Antilles, including the nominal type locality in Martinique, nest within the mainland population of *M. molossus*.

There is a phylogenetic split between northern and southern Dominican Republic for 3 species of bats as recently reported by Lim et al. (in press) based on COI diversity. Varying degrees of sequence divergence for *Macrotus waterhousii* (7.6%), *Pteronotus pusillus* (3.4%), and *P. quadridens* (1.3%) suggest a persistent barrier to gene flow. This geogeographic separation coincides with the Miocene paleo-islands that eventually formed Hispaniola approximately 10 million years ago by tectonic activity and subsequent fluctuations in sea levels (Iturralde-Vinent and MacPhee 1999; Graham 2003). Recent molecular studies of lizards (Gifford, et al. 2004), birds (Townsend et al. 2007), and rodents (Brace et al. 2012) have also recovered this geographic break.

In summary, molecular phylogenetic analysis of Caribbean bats and closely related continental species identify 4 general patterns of biogeography in the Neotropics and the

discovery of cryptic species diversity. (1) Phylogeographic structuring is seen within some widely distributed species with populations in the Caribbean and Central and North America. (2) Recent systematic revisions identify Lesser Antillean endemics as closely related to taxa in South America. (3) Both Caribbean endemic taxa and more broadly occurring genera have species allopatrically distributed on islands. (4) There is a phylogenetic separation of northern and southern Hispaniolan populations in 3 species of bats.

DNA barcoding and other molecular methods are discovering an underestimation of biodiversity that will contribute to a better understanding of the evolution of bats and other organisms in the Caribbean and throughout the world. However, comprehensive systematic revisions are needed to document this increase in taxonomic diversity. This study also highlights a sampling bias towards new species descriptions on islands, primarily in the Paleotropics (Reeder et al. 2007), but there is still much to be discovered and studied in the insular Neotropics. As the third hottest hotspot (Myers et al. 2000), good estimations of biodiversity are necessary for prioritizing conservation initiatives in the Caribbean.

Acknowledgements

I thank my field and research collaborators in the Caribbean, including Lina Arcila, Livia Loureiro, Nate Upham, Jorge Brocca, and Francois Catzeflis, for contributing specimens to this review paper. Thanks also to the National Environment and Planning Agency in Jamaica and Ministerio de Medio Ambiente y Recursos Naturales in Dominican Republic for research and export permits (No. VAPB-01095). Appreciation is extended to 2 anonymous reviewers and the Associate Editor, Beth Clare, for constructive comments that improved the paper. Liliana

Dávalos kindly provided collecting locality information for the Dominican Republic. This project was supported by the Life In Crisis: Schad Gallery of Biodiversity Research Fund and the Collections & Research Fieldwork Fund at the Royal Ontario Museum.

Table 1. Species of bats from Jamaica, Dominican Republic, and Martinique with sample sizes used in the molecular phylogenetic analysis of genetic variation based on DNA barcodes. If “0”, the species occurs on the island but no sample was available in this study. An unfilled cell indicates that the species is not found on the island.

Species	Jamaica	Dominican Republic	Martinique
<i>Ardops nichollsi</i>			6
<i>Ariteus flavescens</i>	0		
<i>Artibeus jamaicensis</i>	12	26	1
<i>Artibeus schwartzi</i>			3
<i>Brachyphylla cavernarum</i>			4
<i>Brachyphylla pumila</i>		3	
<i>Chilonatalus micropus</i>	2	0	
<i>Eptesicus fuscus</i>	0	2	
<i>Erophylla bombifrons</i>		14	
<i>Erophylla sezekorni</i>	1		
<i>Eumops auripendulus</i>	0		
<i>Eumops glaucinus</i>	0		
<i>Glossophaga sorcina</i>	10		
<i>Lasiurus borealis</i>		4	
<i>Lasiurus degelidus</i>	0		
<i>Macrotus waterhousii</i>	0	12	
<i>Molossus molossus</i>	11	8	1
<i>Monophyllus redmani</i>	4	15	
<i>Monophyllus plethodon</i>			3
<i>Mormoops blainvillii</i>	13	9	
<i>Myotis martiniquensis</i>			5
<i>Natalus jamaicensis</i>	0		
<i>Natalus major</i>		1	
<i>Natalus stramineus</i>			0

<i>Noctilio leporinus</i>	0	3	0
<i>Nyctinomops macrotis</i>	0	0	
<i>Phyllonycteris aphylla</i>	0		
<i>Phyllonycteris poeyi</i>		2	
<i>Phyllops falcatus</i>		14	
<i>Pteronotus davyi</i>			2
<i>Pteronotus macleayi</i>	11		
<i>Pteronotus parnellii</i>	8		
<i>Pteronotus pusillus</i>		7	
<i>Pteronotus quadridens</i>	9	12	
<i>Sturnira lilium</i>			5
<i>Tadarida brasiliensis</i>	0	0	3

Draft

Table 2. Sequence divergence based on Kimura 2-paramater model of nucleotide substitutions for bat diversity in the Caribbean. Species abbreviations in order of appearance in table are: *Ardops nichollsi*, *Artibeus schwartzi*, *Artibeus jamaicensis*, *Brachyphylla cavernarum*, *Molossus molossus*, *Monophyllus plethodon*, *Myotis martiniquensis*, *Pteronotus davyii*, *Sturnira lilium*, *Tadarida brasiliensis*, *Brachphylla pumila*, *Eptesicus fuscus*, *Erophylla bombifrons*, *Lasiurus minor*, *Macrotus waterhousii*, *Monophyllus redmani*, *Mormoops blainvillei*, *Natalus major*, *Noctilio leporinus*, *Phyllonycteris poeyi*, *Phyllops falcatus*, *Pteronotus pusillus*, *Pteronotus quadridens*, *Chilonatalus micropus*, *Erophylla sezekorni*, *Glossophaga soricina*, *Pteronotus macleayii*, *Pteronotus parnellii*, and *Brachyphylla pumila*.
