Robert Robinson§  Nicholas Wormald¶

November 2, 2000

1 Introduction

This paper deals with computational problems involving Hamilton cycles in random regular graphs. Thus let \( G = G(r, n) \) denote the set of \( r \)-regular (simple) graphs with vertex set \( [n] = \{1, 2, \ldots, n\} \). While it is NP-Complete to tell whether or not a cubic \( (r = 3) \) graph has a Hamilton cycle, it has been known for some time that for \( r \) fixed but sufficiently large, \( G \) chosen at random from \( G(r, n) \) is Hamiltonian \textit{whp}1, see Bollobás [2], Fenner and

1An event \( \mathcal{E}_n \) is said to occur \textit{whp} (with high probability) if \( \Pr(\mathcal{E}_n) = 1 - o(1) \) as \( n \rightarrow \infty \).
Frieze [5]. These results were non-constructive and Frieze [6] described an 
$O(n^3 \log n)$ time algorithm that found a Hamilton cycle \textbf{whp}, provided $r \geq 85$. Thus until quite recently it was not known whether or not a random cubic graph was Hamiltonian \textbf{whp}. (Experiments with the algorithm of \cite{6} strongly suggested that it was.)

In two recent papers Robinson and Wormald \cite{12}, \cite{13} used a second moment approach and showed that random $r$-regular graphs are Hamiltonian \textbf{whp} for $r \geq 3$. Their proof is non-constructive and the purpose of this paper is to provide corresponding algorithmic results. We abandon the rotation-extension approach of \cite{6} in favour of an approach based on rapidly mixing Markov chains. We prove

\textbf{Theorem 1} Let $r \geq 3$ be fixed and let $G$ be chosen uniformly at random from $G(r, n)$. There is a polynomial time algorithm \texttt{FIND} which constructs a Hamilton cycle in $G$ \textbf{whp}.

For a graph $G$ let $\text{HAM}(G)$ denote the set of Hamilton cycles of $G$. Assuming $\text{HAM}(G) \neq \emptyset$, a \textit{near uniform generator} for $\text{HAM}(G)$ is a randomised algorithm which on input $\epsilon > 0$ outputs a cycle $H \in \text{HAM}(G)$ such that for any fixed $H_1 \in \text{HAM}(G)$

$$\left| \Pr(H = H_1) - \frac{1}{|\text{HAM}(G)|} \right| \leq \frac{\epsilon}{|\text{HAM}(G)|}.$$  \hspace{1cm} (1)

The probabilities here are with respect to the algorithm’s random choices, as $G$ is considered fixed in (1). The algorithm is polynomial if it runs in time polynomial in $n$ and $1/\epsilon$. 

2
Theorem 2 Let $r \geq 3$ be fixed. There is a procedure $\text{GENERATE}$ such that if $G$ is chosen uniformly at random from $\mathcal{G}(r, n)$ then w.h.p $\text{GENERATE}$ is a polynomial time generator for $\text{HAM}(G)$.

Given a polynomial time generator for a set $X$ one can usually estimate its size. This notion is made precise in Jerrum, Valiant and Vazirani [10]. The results there are based on the notion of self-reducibility (Schnorr [14]), which we do not have here. On the other hand, our method of proof does lead to an FPRAS (Fully Polynomial Randomised Approximation Scheme) for almost every $G \in \mathcal{G}(r, n)$.

An $\text{FPRAS}$ for $\text{HAM}(G)$ is a randomised algorithm which on input $\epsilon, \delta > 0$ produces an estimate $Z$ such that

\[
\Pr \left( \left| \frac{Z}{|\text{HAM}(G)|} - 1 \right| \geq \epsilon \right) \leq \delta. \tag{2}
\]

Again, the probabilities in (2) are with respect to the algorithm’s choices. The running time of the algorithm is polynomial in $n, 1/\epsilon$ and $\log(1/\delta)$.

Theorem 3 Let $r \geq 3$ be fixed. There is a procedure $\text{COUNT}$ such that if $G$ is chosen uniformly at random from $\mathcal{G}(r, n)$ then w.h.p $\text{COUNT}$ is an FPRAS for $\text{HAM}(G)$.

These results can be extended to random regular digraphs, see Frieze, Molloy and Cooper [7], Janson [8] for the non-constructive counterparts.

Our final result concerns a problem left open by Broder, Frieze and Shamir [4]. A graph $G$ with vertex set $[n]$ is obtained by adding a random perfect matching $M$ to a random Hamilton cycle $H$. The problem is to find a Hamilton
cycle in $G$ without knowing $H$. One motivation for this problem is in the
design of authentication protocols. Our positive result on finding a Hamilton
cycle can be viewed as a negative result for such a protocol.

**Theorem 4** Let $n$ be even and let $G$ be obtained as the union of a random
perfect matching $M$ and a random (disjoint) Hamilton cycle $H$. Applying
FIND to $G$ will lead to the construction of a Hamilton cycle \( \text{whp} \).

The next section outlines the proof of these results and the remaining sections
fill in the missing details.

## 2 Outline proofs of Theorems

### 2.1 Configurations

Initially we will not work directly with $G(r, n)$. Instead we will use the
configuration model as developed by Bender and Canfield [1] and Bollobás [3].
Thus let $W = [n] \times [r]$ \((W_v = v \times [r] \text{ represents } r \text{ half edges incident with vertex } v \in [n].)\) The elements of $W$ are called points and a 2-element subset
of $W$ is called a pairing. A configuration $F$ is a partition of $W$ into $rn/2$
pairings. We associate with $F$ a multigraph $\mu(F) = ([n], E(F))$ where, as a
multi-set,

\[
E(F) = \{(v, w) : \{(v, i), (w, j)\} \in F \text{ for some } 1 \leq i, j \leq r\}.
\]

(Note that $v = w$ is possible here.)

Let $\Omega$ denote the set of possible configurations. Thus

\[
|\Omega| = P(rn)
\]
where

\[ P(2m) = \frac{(2m)!}{m!2^m}. \]

We say that \( F \) is \textit{simple} if the multigraph \( \mu(F) \) has no loops or multiple edges. Let \( \Omega_0 \) denote the set of simple configurations.

We turn \( \Omega \) into a probability space by giving each element the same probability. The main properties that we need of this model are

\begin{itemize}
    \item \textbf{P1} Each \( G \in \mathcal{G}(n, r) \) is the image (under \( \mu \)) of exactly \( (r!)^n \) simple configurations.
    \item \textbf{P2} \( \Pr(F \in \Omega_0) \approx e^{-(r^2-1)/4}. \)
\end{itemize}

(Here \( \alpha \approx \beta \) means that \( \alpha/\beta \to 1 \) as \( n \to \infty \).)

Suppose now that \( \mathcal{A}^* \) is a property of configurations and \( \mathcal{A} \) is a property of graphs such that when \( F \in \Omega_0, \mu(F) \in \mathcal{A} \) implies \( F \in \mathcal{A}^* \). Then P1 and P2 imply

\[ \Pr(G \in \mathcal{A}) \leq (1 + o(1))e^{(r^2-1)/4} \Pr(F \in \mathcal{A}^*) \]

where \( G \) is chosen randomly from \( \mathcal{G} \) and \( F \) is chosen randomly from \( \Omega \). We will \textit{generally} use this to prove

\[ \Pr(F \in \mathcal{A}^*) = o(1) \text{ implies } \Pr(G \in \mathcal{A}) = o(1). \]  

(3)

\subsection{2.2 Generating and counting}

We now begin the proof proper. For \( F \in \Omega \) let

\[ Z_H = Z_H(F) = |\text{HAM}(\mu(F))|. \]
Then
\[ E(Z_H) = \frac{H(n, r) P((r - 2)n)}{P(rn)}, \tag{4} \]
where
\[ H(n, r) = \frac{(n - 1)!}{2} (r(r - 1))^n. \]

**Explanation:** \( H(n, r) \) is the number of sets of \( n \) pairings which would be projected by \( \mu \) to a Hamilton cycle (an \( H \)-configuration). \( P((r - 2)n)/P(rn) \) is the probability that a given \( H \)-configuration appears in \( F \).

Note that Stirling’s approximation gives
\[ E(Z_H) \approx \sqrt{\frac{\pi}{2n}} \left( (r - 1) \left( \frac{r - 2}{r} \right)^{(r-2)/2} \right)^n. \]
which grows exponentially with \( n \) for \( r \geq 3 \).

Using the method of Robinson and Wormald we prove (Section 5) that
\[ Z_H \geq n^{-1} E(Z_H) \text{ \ whp,} \tag{5} \]
which by (3) implies
\[ |\text{HAM}(G)| \geq \frac{1}{n} E(Z_H) \text{ \ whp.} \tag{6} \]

A 2-factor of a graph \( G \) is a set of vertex disjoint cycles which contain all vertices. Let \( 2\text{FACTOR}(G) \) denote the set of 2-factors of \( G \). Then
\[ \text{HAM}(G) \subseteq 2\text{FACTOR}(G). \]

---

\(^2\)Robinson and Wormald prove this for \( r = 3 \) but decline to do it for \( r \geq 4 \). They proceed indirectly. This has advantages and disadvantages. The advantage is that they show that a random \( r + 1 \)-regular graph is close to a random \( r \)-regular graph plus a random matching (\( r \geq 2 \)). But for our purposes, (6) is what is needed.
For \( F \in \Omega \) let
\[
Z_f = Z_f(F) = |2\text{FACTOR}(\mu(F))|.
\]
Now
\[
\mathbb{E}(Z_f) \leq \frac{\binom{r}{2}^n P(2n)P((r-2)n)}{P(rn)}.
\] (7)

**Explanation:** there are \( \binom{r}{2}^n \) ways of choosing two points from each \( W_\ell \).
There are then \( P(2n) \) ways of pairing these points. If the set \( X \) of \( n \) pairings contains no loops or multiple edges then \( \mu \) projects \( X \) to a 2-factor. The remaining terms give the probability that \( X \) exists in \( F \). We have inequality in (7) as some sets \( X \) do not yield 2-factors and some yield the same. On the other hand all 2-factors of \( G \) arise in this way. By the Markov inequality
\[
Z_f \leq n\mathbb{E}(Z_f) \text{ whp},
\]
which by (3) implies
\[
|2\text{FACTOR}(G)| \leq n\mathbb{E}(Z_f) \text{ whp}. \tag{8}
\]
Now by (4) and (7)
\[
\frac{\mathbb{E}(Z_f)}{\mathbb{E}(Z_H)} \leq \frac{(2n)!}{2^{2n-1}n!(n-1)!} \leq 2n^{1/2}. \tag{9}
\]
Combining (6) and (8) we obtain
\[
\frac{|\text{HAM}(G)|}{|2\text{FACTOR}(G)|} \geq \frac{1}{2n^{n/2}} \text{ whp}. \tag{10}
\]
We will show in Section 3 that \( \text{whp} \) there is a polynomial time generator and an FPRAS for \( 2\text{FACTOR}(G) \). This and (10) easily verifies Theorems 1, 2 and 3. Indeed we estimate \( |2\text{FACTOR}(G)| \) and the ratio \( |\text{HAM}(G)|/|2\text{FACTOR}(G)| \),
The former is estimated by the assumed FPRAS and the latter by generating $O(n^{5/2}/\epsilon^2)$ 2-factors and computing the proportion that are Hamilton cycles ($\epsilon$ is the required relative accuracy).

### 2.3 Hidden Hamilton cycles

Let $X = \{(H, M) : H \text{ is a Hamilton cycle, } M \text{ is a perfect matching of } K_n \text{ and } H \cap M = \emptyset\}$. Consider $X$ to be a probability space in which each element is equally likely. Let $\Pr_1$ refer to probabilities in this space and $\Pr_0, E_0$ refer to probability and expectation with respect to $F$ chosen randomly from $\Omega_0$.

Let $A = \{F \in \Omega_0 : \text{GENERATE is not a polynomial time generator for HAM(} \mu(F)\text{)}\}$ and $\hat{A} = \{(H, M) \in X : \text{GENERATE is not a polynomial time generator for HAM}(H \cup M)\}$ be the corresponding subset of $X$. Now for each $(H, M) \in X$ there are $6^n$ configurations $F$ for which $\mu(F) = H \cup M$ and for each $F \in \Omega_0$ there are $Z_H(F)$ corresponding pairs $(H, M)$ in $X$. Thus, where $1_A$ is the indicator function of the set $A$:

$$
\Pr_1(\hat{A}) = \sum_{(H, M) \in \hat{A}} \frac{1}{|X|} = \sum_{F \in A} \frac{Z_H(F)}{6^n|X|} = \frac{1}{E_0(Z_H)} E_0(1_A Z_H) \quad \text{since } 6^n|X| = |\Omega_0| E_0(Z_H) \\
\leq \frac{1}{E_0(Z_H)} \sqrt{E_0(1_A^2) E_0(Z_H^2)}.
$$

---

\[3\] This elegant use of the Cauchy-Schwarz inequality was pointed out to us by Svante Janson.
Robinson and Wormald proved [11] that

$$E_0(Z_H^2) \approx \frac{3}{e} E_0(Z_H)^2.$$ 

Hence

$$\Pr_1(\hat{A}) \leq (1 + o(1)) \sqrt{\frac{3}{e} \Pr_0(A)} = o(1),$$

(11)

by Theorem 1.

3 Generating and counting 2-factors

For any graph $G = (V, E)$, a construction of Tutte [15] gives a graph $G' = (V', E')$ such that the perfect matchings in $G'$ correspond in a natural fashion to the 2-factors of $G$. Specifically, (assuming $G$ is $r$-regular) for each vertex $v \in V$ we have a complete bipartite graph $H_v \cong K_{r,r-2}$ with bipartition

$$U_v = \{u_{v,w} : \{v, w\} \in E\}, \quad W_v = \{w_{v,i} : 1 \leq i \leq r - 2\}.$$ 

Now $V' = \bigcup_{v \in V} (U_v \cup W_v)$ and $E'$ contains the edge set of $H_v$ for each $v \in V$. Additionally, for each edge $\{v, w\} \in E$ we have a unique edge $\{u_{v,w}, u_{w,v}\} \in E'$. We will call these the $G$-edges of $G'$ and the remainders the $H$-edges.

In any perfect matching in $G'$ exactly two vertices in $U_v$ will not be matched by $H$-edges. They must therefore be matched by two $G$-edges incident with $H_v$. Thus the $n$ $G$-edges in the matching correspond to a 2-factor $K$ in $G$. For each such choice of edges, the remaining $(r - 2)n$ $H$-edges can be chosen in $(r - 2)!^n$ ways. Therefore each 2-factor in $G$ corresponds to $(r - 2)!^n$ perfect matchings in $G'$. In particular, by generating a near uniform perfect
matching $G'$ we can generate a near uniform 2-factor of $G$. Similarly, by approximately counting perfect matchings in $G'$, we can approximately count 2-factors in $G$.

The problem of generating near uniform perfect matchings in a graph $\Gamma$ was studied by Jerrum and Sinclair [9]. They describe an algorithm which runs in time polynomial in $|V(\Gamma)|$, $1/\epsilon$ and $\rho = \rho(\Gamma)$, where $\rho$ is the ratio of the number of near perfect to perfect matchings of $\Gamma$ (a near perfect matching covers all but two vertices). In light of this we have only to show that whp $\rho(G')$ is bounded by a polynomial in $n$.

Let $\nu_p$ and $\nu_{np}$ denote the number of perfect and near perfect matchings in $G'$, assuming $G$ is chosen at random from $\mathcal{G}(r,n)$. Then, from (6), we have

$$\nu_p \geq \frac{(r - 2)!^n}{n} \mathbb{E}(Z_H) \ \text{whp}.$$  

To estimate $\nu_{np}$ we consider the $G$-edges of some near perfect matching $M'$ of $G$. Let $M$ denote the corresponding set of edges in $G$ itself. It is straightforward to verify that the subgraph $G(M)$ induced by $M$ has

(i) $n - 2$ vertices of degree 2, and

(ii) 2 vertices with degrees $d_1, d_2 \in \{0, 1, 2, 3, 4\}$ where $d_1 + d_2 = 2, 4$ or 6.

Let $Z_{nf}$ denote the number of subgraphs of $G$ satisfying (i) and (ii). Clearly

$$\nu_{np} \leq (r - 2)!^{n-2}(r!)^2 Z_{nf}$$  \hspace{1cm} (12)

and a (crude) argument similar to that for (7) yields

$$\mathbb{E}(Z_{nf}) \leq \frac{\binom{n}{2} (r!)^2 \binom{r}{2}^{n-2} \sum_{k=-1}^{1} P(2(n+k)) P((r-2)n-2k)}{P(rn)}.$$
Applying (12) and the Markov inequality we see that
\[ \nu_{np} \leq n(r - 2)!^{n-2}(r!)^2 \mathbb{E}(Z_{nf}) \quad \text{whp} \]
and so whp
\[
\rho(G') \leq \frac{n^2 \binom{n}{2} (r - 2)!^{n-2} r^8 \sum_{k=1}^{n} P(2(n + k))P((r - 2)n - 2k)}{(r - 2)!^{n} \mathbb{E}(Z_{H})P(rn)}
= O(n^{9/2}),
\]

as required.

4 The Variance of $Z_H$

The method of Robinson and Wormald is an analysis of variance. We will partition the probability space $\Omega$ into groups according to the number of cycles of each size. We will then show that $\mathbf{Var}(Z_H)$ can be “explained” almost entirely by the variance between groups. Thus, within most groups $Z_H$ is concentrated around its mean, which in most groups is “close” to $\mathbb{E}(Z_H)$. In this section we compute the variance of $Z_H$.

We will from now on assume that $r \geq 4$. The case $r = 3$ has been dealt with in [12]. The calculations there are done directly on $G(3, n)$.

We will count the number of potential pairs of Hamilton cycles by counting the number of pairs $(H, H')$ of $H$-configurations whose intersection is a set of $a$ paths containing a total of $k$ edges, and summing over all feasible $a, k$. If $H, H'$ coincide, then we have $k = n$ and we take $a = 0$. Thus:

\[
\mathbb{E}(Z_H^2) = \mathbb{E}(Z_H) \sum_{k, a} N(k, a) P((r - 4)n + 2k)/P((r - 2)n),
\]

(13)
where $N(k, a)$ is the number of ways of selecting $H'$ given $H$, $k$ and $a$. Note that this quantity is independent of $H$.

**Explanation:** for each fixed $H$, $k$, $a$ the number of possible $H'$ is independent of $H$. Taking out the factor $E(Z_H)N(k, a)$ leaves us with $\Pr(H' \mid H)$ which comprises the last two factors.

**Claim 1:** The number of ways of selecting $k$ edges from $H$ consisting of $a$ paths is

$$\frac{an}{k(n-k)} \binom{k}{a} \binom{n-k}{a},$$

provided we interpret $\frac{an}{k(n-k)}$ as 1 when $a = 0$ (equivalently $k = 0$ or $k = n$).

**Proof** We will assume $a > 0$ and $k < n$. Fix an orientation of $H$. Remove any edge of $H$ and insist that it is not one of the $k$ edges. We now have a path of length $n - 1$ from which we must choose $k$ edges forming $a$ paths. There are $\binom{k-1}{a-1}$ ways to choose the lengths of the paths, and $\binom{n-k}{a}$ ways to pick their initial vertices. There were $n$ ways to choose the edge that was removed, and each choice of paths had $n-k$ eligible choices for this edge. Therefore, the number of ways of selecting the paths is $\frac{n}{n-k} \binom{k-1}{a-1} \binom{n-k}{a} = \frac{an}{k(n-k)} \binom{k}{a} \binom{n-k}{a}$. 

**Claim 2:** Given our choice of the $k$ edges of $H$, the number of ways to complete $H'$ is:

$$\left(\frac{2(r-2)}{r-3}\right)^a H(n-k, r-2).$$

**Proof** Imagine that each of these $a$ paths is contracted to a single vertex. The selection of a Hamilton cycle $H'$ extending the chosen fragments of $H$ can be divided into two steps: (i) select a Hamilton cycle on $n-k$ vertices
which joins up all the (contracted) fragments, and then (ii) select a way of splicing in the (expanded) fragments to obtain a full \( n \)-edge \( H \)-configuration \( H' \). The number of choices in (i) is simply \( H(n - k, r - 2) \), where we must interpret \( H(0, r - 2) \) as 1, while for (ii) it is \( (2(r - 2)/(r - 3))^a \). (For each fragment we may choose a direction of traversal; then, on expanding each fragment from a point to a path, the number of ways of connecting \( H' \) to the endpoints of a fragment is increased from \((r - 2)(r - 3)\) — as counted by the formula for \( H(n - k, r - 2) \) — to \((r - 2)^2\).)

Substituting for \( N(k, a) \) in (13), and applying (4) and Stirling’s formula, we have

\[
E(Z_H^2) = E(Z_H) \sum_Q \frac{an}{k(n-k)} \binom{k}{a} \binom{n-k}{a} \left( \frac{2(r-2)}{r-3} \right)^a \\
\times \frac{H(n-k, r-2) P((r-4)n + 2k)}{P((r-2)n)} \\
\geq \frac{\sqrt{\pi n}}{4} \left( \frac{n}{e} \right)^{(r-2)n/2} \left( \frac{(r-1)(r-2)(r-3)}{2(r-4)/2} \right)^n \\
\times \sum_Q \frac{a}{k(n-k)^2} T_{a,k},
\]

where

\[
T_{a,k} = \frac{k! (n-k)! (r-4)n + 2k)! (r-2)^{a-k} 2^{a-k}}{a! (k-a)! (n-k-a)! ((r-4)n/2 + k)! (r-3)^{a+k}},
\]

and

\[
Q = \{(k, a) \mid a, k - a, n - k - a \geq 0 \}.
\]

It is straightforward to check that we can ignore all terms on the border of \( Q \), as they each contribute \( o(n^{-2} E(Z_H^2)) \), and so we define

\[
Q' = \{(k, a) \mid a, k - a, n - k - a > 0 \}.
\]
Now set $\kappa = \frac{k}{n}, \alpha = \frac{\alpha}{n}$. Using Stirling’s approximation, we have:

\[
\mathbf{E}(Z^2_H) \approx \frac{1}{4\pi^2} \left( \frac{2(r^2-4)(r-1)(r-2)(r-3)}{r(r-2)/2} \right)^n \\
\times \sum_{q'} F^n \lambda(1 + \epsilon),
\]

where $F = F_r(\kappa, \alpha)$ is defined by

\[
F = \frac{2^{\kappa+\alpha}(r-2)^{\alpha-\kappa}g(\kappa)g(1-\kappa)^2g(2-2+\kappa)}{(r-3)^{\kappa+\alpha}g(\alpha)^2g(\kappa-\alpha)g(1-\kappa-\alpha)},
\]

with $g(x) = x^x$,

\[
\lambda = (\kappa(\kappa - \alpha)(1 - \kappa - \alpha)(1 - \kappa)^2)^{-\frac{1}{2}},
\]

and

\[
\epsilon = O \left( \frac{1}{a} + \frac{1}{k-a} + \frac{1}{n-k-a} \right).
\]

We extend the domain of $F_r$ to

\[
R = \{(\alpha, \kappa) \mid \alpha, \kappa - \alpha, 1 - \kappa - \alpha \geq 0\},
\]

by defining $g(0) = 1$. It is straightforward to verify that $F_r$ is continuous over $R$. We now wish to find its maximum, so we will look for the critical points of $F_r$ in the interior of $R$. We set the partial derivatives of $\ln F_r$ with respect to $\kappa$ and $\alpha$ equal to 0, yielding the two equations:

\[
\kappa(1 - \kappa - \alpha)(r - 4 + 2\kappa) - (r - 2)(r - 3)(1 - \kappa)^2(\kappa - \alpha) = 0,
\]

and

\[
(r - 3)\alpha^2 - 2(r - 2)(\kappa - \alpha)(1 - \kappa - \alpha) = 0.
\]
It is easily verified that $\kappa = \kappa_0 = 2/r$, $\alpha = \alpha_0 = 2(r-2)/r(r-1)$ is a solution of the simultaneous equations (16) and (17). As we now show, this solution is the only one in the interior of $R$.

Solving equation (16) for $\alpha$, noting that the equation is linear in $\alpha$, we obtain

$$\alpha = \frac{\kappa(k - 1)[(r^2 - 5r + 8)\kappa - (r^2 - 6r + 10)]}{Q_r(k)},$$

where

$$Q_r(k) = (r^2 - 5r + 4)\kappa^2 - (2r^2 - 9r + 8)\kappa + (r^2 - 5r + 6).$$

Substituting this expression for $\alpha$ in equation (17) yields an equation of the form $P_r(\kappa)/Q_r(\kappa)^2 = 0$, where

$$P_r(\kappa) = (r - 3)\kappa(\kappa - 1)^2(\kappa r - 2)P_r(\kappa),$$

and

$$P_r'(\kappa) = (r^3 - 10r^2 + 25r - 16)\kappa^2 + (-2r^3 + 16r^2 - 36r + 22)\kappa$$

$$+(r^3 - 8r^2 + 20r - 16).$$

Clearly, any solution to (16) and (17) will also be a solution to $P_r(\kappa) = 0$.

When $\kappa = \kappa_0 = 2/r$, the solution $\alpha = \alpha_0$ is unique, except in the case $r = 4$, when equation (16) holds for all $\alpha$ and equation (17) allows the additional solution $\alpha = 1$ which is not in the interior of $R$. Clearly the roots $\kappa = 0$ and $\kappa = 1$ do not lead to solutions in the interior of $R$.

We have considered all roots of $P_r(\kappa)$, except those given by the quadratic (19). Our aim is to show that all such roots $\kappa$ lead to solution pairs $(\alpha, \kappa)$ that do not lie in the interior of $R$. In analysing the quadratic $P_r'(\kappa)$, it is convenient
to assume \( r \geq 7 \), and leave \( r = 4, 5, 6 \) as special cases to be treated later. We first establish a lower bound on roots \( \kappa \) of equation (19), by recasting (19) in the form

\[
P^I_r(\kappa) = (r^3 - 10r^2 + 25r - 16)(\kappa - 1)^2 - (4r^2 - 14r + 10)\kappa + (2r^2 - 5r).
\]

Under the assumption \( r \geq 7 \), the factor \( r^3 - 10r^2 + 25r - 16 \) is strictly positive, and hence any root \( \kappa \) of \( P^I_r(\kappa) = 0 \) must satisfy

\[
\kappa \geq \frac{2r^2 - 5r}{4r^2 - 14r + 10} > \frac{1}{2}.
\]

Now, from equation (18),

\[
1 - \kappa - \alpha = \frac{-(r - 2)(r - 3)(2\kappa - 1)(\kappa - 1)^2}{Q_r(\kappa)}.
\] (20)

In the light of our lower bound on \( \kappa \), we see immediately that the numerator of (20) is negative. We show that, for \( r \geq 7 \), the denominator of (20) is positive, from which it follows that \( 1 - \kappa - \alpha \) is negative, and the point \((\alpha, \kappa)\) cannot lie in the interior of \( R \).

By direct calculation,

\[
(2r - 5)Q_r(\kappa) - 2P^I_r(\kappa)
= (5r^2 - 17r + 12)\kappa^2 - (4r^2 - 11r + 4)\kappa + (r^2 - 3r + 2).
\] (21)

The discriminant of quadratic (21) is \(-(2r - 5)(r - 4)(2r^2 - 7r + 4)\), which is negative for all \( r > 4 \); furthermore, the leading coefficient of (21) is positive under the same condition on \( r \). It follows that \((2r - 5)Q_r(\kappa) - 2P^I_r(\kappa)\) is positive for all \( r > 4 \) and all \( \kappa \), and hence that \( Q_r(\kappa) \) is positive for all \( r > 4 \).
and all $\kappa$ satisfying $P_\kappa''(\kappa) = 0$. This verifies the claim that the denominator of (20) is positive, and completes the analysis of the case $r \geq 7$.

The case $r = 5$ may be eliminated by noting that, of the two roots $\kappa = (-1 \pm \sqrt{10})/4$ of (19), one is negative, and the other yields a corresponding value for $\alpha$ that is greater than 1. A similar argument eliminates the case $r = 6$. When $r = 4$, the two roots of (19) are $\kappa = 0$ and $\kappa = 1/2$; the former leads to a solution not in the interior $R$, while the latter is just a repeat of the root $\kappa = \kappa_0 = 2/r$ that we have already considered.

Now that we have established $(\kappa_0, \alpha_0)$ as the only critical point of $F_r$ in $R$, other than $(0, 0)$, we will see that it is a local maximum, and it will follow that we can ignore all $(\kappa, \alpha)$ not nearby $(\kappa_0, \alpha_0)$. Set

$$\delta_k = \frac{k - \kappa_0 n}{\sqrt{n}}, \delta_\alpha = \frac{\alpha - \alpha_0 n}{\sqrt{n}},$$

and perform a Taylor expansion of $\ln(F_r(\kappa, \alpha))$ around $(\kappa_0, \alpha_0)$, yielding:

$$F^n = F_r(\kappa_0, \alpha_0)^n \exp(-(A\delta_k^2 + B\delta_k\delta_\alpha + C\delta_\alpha^2) + \text{cubic terms and greater}),$$

where

$$A = \frac{1}{2(\kappa_0 - \alpha_0)} + \frac{1}{2(1 - \kappa_0 - \alpha_0)} - \frac{1}{2\kappa_0} - \frac{1}{1 - \kappa_0} - \frac{1}{r - 4 + 2\kappa_0},$$

$$B = \frac{1}{1 - \kappa_0 - \alpha_0} - \frac{1}{\kappa_0 - \alpha_0},$$

$$C = \frac{1}{\alpha_0} + \frac{1}{2(\kappa_0 - \alpha_0)} + \frac{1}{2(1 - \kappa_0 - \alpha_0)}.$$

Substituting $\kappa_0 = 2/r, \alpha_0 = 2(r - 2)/r (r - 1)$ we get:

$$A = \frac{r(r^4 - 9r^3 + 28r^2 - 34r + 16)}{4(r - 2)^2(r - 3)},$$

17
\[ B = -\frac{r(r-1)^2(r-4)}{2(r-2)(r-3)}, \]
\[ C = \frac{r(r-1)^2}{4(r-3)}. \]

The determinant \( D = 4AC - B^2 \) of the Hessian of \( A\delta_k^2 + B\delta_k\delta_a + C\delta_a^2 \) is

\[ D = \frac{r^3(r-1)^2}{4(r-2)(r-3)}. \]

Now it is easily checked that \( A > 0 \) for \( r \geq 4 \) and since \( D > 0 \) we have that \( F \) is strictly concave, and \((\kappa_0, \alpha_0)\) is a local maximum. It follows that we can ignore all terms of (15) outside of

\[ X = \{(k, a) \mid |k - \kappa_0 n|, |a - \alpha_0 n| \leq \sqrt{n \log n}\}. \]

Now,

\[ F_r(\kappa_0, \alpha_0) = \frac{(r-1)(r-2)^{r-3}}{2^{(r-1)/2}(r-3)r^{(r-2)/2}}, \]

and so by (15),

\[
\mathbb{E}(Z_{H}^2) \approx \frac{1}{4n^2} \left( \frac{2^{(r-4)/2}(r-1)(r-2)(r-3)}{r^{(r-2)/2}} \right)^n \sum_X F(\kappa, \alpha)^n \lambda \]

\[
\approx \frac{1}{4n^2} \left( \frac{2^{(r-4)/2}(r-1)(r-2)(r-3)}{r^{(r-2)/2}} \right)^n \times \left( \frac{r^{5/2}(r-1)}{2(r-2)^3/2(r-3)^{1/2}} \right)^n F(\kappa_0, \alpha_0)^n \]

\[
\times n \int_X \exp\{-(A\delta_k^2 + B\delta_k\delta_a + C\delta_a^2)\} \, d\delta_k \, d\delta_a \]

\[
\approx \frac{1}{4n} \left( \frac{r^{5/2}(r-1)}{2(r-2)^3/2(r-3)^{1/2}} \right). \]
\[ \times \left( \frac{r - 2}{r} \right)^{r-2} \left( r - 1 \right)^2 \right)^n \frac{2\pi}{\sqrt{D}} \]

\[ = \frac{\pi r}{2(r - 2)n} \left( \frac{(r - 2)}{r} \right)^{r-2} \left( r - 1 \right)^2 \right)^n , \]

and comparing with (4), we have

\[ \frac{\mathbf{E}(Z_H^2)}{\mathbf{E}(Z_H)^2} \approx \frac{r}{r - 2}. \] (22)

5 Bounding \( Z_H \) whp

In the following, \( b, x \) are considered to be arbitrary large fixed positive integers. Let \( C_\ell \) denote the number of \( \ell \)-cycles of \( \mu(F) \) for \( \ell \geq 1 \). We will be concerned mainly with \( C_\ell \) where \( \ell \) is odd. For \( \mathbf{c} = (c_1, c_2, \ldots, c_b) \in N^b \), where \( N = \{0, 1, 2, \ldots\} \), let group \( \Omega_{\mathbf{c}} = \{ F \in \Omega : C_{2k - 1} = c_k, 1 \leq k \leq b \} \). Let

\[ \lambda_k = \frac{(r - 1)^{2k - 1}}{2(2k - 1)}. \]

It is straightforward to show that the \( C_\ell, \ell \geq 1 \), are asymptotically independent Poisson variables with mean \( (r - 1)^\ell / 2\ell \); thus if \( \mathbf{c} \) is fixed, then

\[ \pi_{\mathbf{c}} = \mathbf{Pr}(F \in \Omega_{\mathbf{c}}) = \prod_{k=1}^{b} \frac{\lambda_k^{c_k} e^{-\lambda_k}}{c_k!}. \]

Now let

\[ S(x) = \{ \mathbf{c} \in N^b : c_k \leq \lambda_k + x\lambda_k^{2/3}, 1 \leq k \leq b \}, \]

and

\[ \Omega = \bigcup_{\mathbf{c} \notin S(x)} \Omega_{\mathbf{c}}. \]
Let

\[ \pi = \Pr(F \in \overline{\Omega}). \]

For \( c \in N^b \) let

\[ E_c = \mathbb{E}(Z_H \mid F \in \Omega_c) \]

and

\[ V_c = \text{Var}(Z_H \mid F \in \Omega_c). \]

Then we have

\[ \mathbb{E}(Z_H^2) = \sum_{c \in N^b} \pi_c V_c + \sum_{c \in N^b} \pi_c E_c^2. \tag{23} \]

The following two lemmas contain the most important observations. Lemma 1 shows that for most groups, the group mean is large and Lemma 2 shows that most of the variance can be explained by the variance between groups.

**Lemma 1** For all sufficiently large \( x \)

(a) \( \pi \leq e^{-\alpha x} \) for some absolute constant \( \alpha > 0 \).

(b) \( c \in S(x) \) implies \( E_c \geq e^{-[\beta + \gamma x]} \mathbb{E}(Z_H) \), for some absolute constants \( \beta, \gamma > 0 \).

**Lemma 2** If \( x \) is sufficiently large then

\[ \sum_{c \in S(x)} \pi_c E_c^2 \geq (1 - be^{-3\gamma x}) \left( 1 - \left( \frac{2}{r - 1} \right)^{2b} \right) \left( \frac{r}{r - 2} \right) \mathbb{E}(Z_H)^2. \]

where \( \gamma \) is as in Lemma 1

20
Hence we have from (22) and (23) and Lemma 2,
\[ \sum_{c \in N^b} \pi_c V_c \leq \delta E(Z_H)^2, \]  
\[ (24) \]
where \( \delta = \left( be^{-3\gamma x} + \left( \frac{2}{r-1} \right)^{2b} \right) \frac{r}{r-2} \). The rest is an application of the Chebycheff inequality. Define the random variable \( \hat{Z}_H \) by
\[ \hat{Z}_H = E_c, \text{ if } F \in \Omega_c. \]

Then for any \( t > 0 \)
\[ \Pr(|Z_H - \hat{Z}_H| \geq t) \leq E((Z_H - \hat{Z}_H)^2/t^2) = \sum_{c \in N^b} \pi_c V_c / t^2 \leq \delta E(Z_H)^2 / t^2 \]

where the last inequality follows from (24).

Put \( t = e^{-(\beta+\gamma x)}E(Z_H)/2 \) where \( \beta, \gamma \) are from Lemma 1. Applying Lemma 1 we obtain that for \( n \) large,
\[ \Pr \left( Z_H \geq \frac{E(Z_H)}{n} \right) \geq \Pr(Z_H \geq e^{-(\beta+\gamma x)}E(Z_H)/2) \geq \Pr(|Z_H - \hat{Z}_H| \leq t \land (F \notin \Omega)) \geq 1 - 4\delta e^{2(\beta+\gamma x)} - \pi \geq 1 - 4\delta e^{2(\beta+\gamma x)} - e^{-\alpha x}. \]

Hence,
\[ \lim_{n \to \infty} \Pr \left( Z_H \geq \frac{E(Z_H)}{n} \right) \geq 1 - \left( 4be^{2\beta - \gamma x} + 4 \left( \frac{2}{r-1} \right)^{2b} e^{2(\beta+\gamma x)} \right) \frac{r}{r-2} e^{-\alpha x}. \]
\[ (25) \]
This is true for all $b, x$ and so the left hand side limit of (25) must in fact be one, proving (5), (putting $b = x^2$ and $x$ arbitrarily large makes the right-hand side of (25) arbitrarily close to 1).

All that remains are the proofs of Lemmas 1 and 2

**Proof of Lemma 2:**

Let $H_0$ be some fixed Hamilton cycle.

$$E_c = \sum_{F \in \Omega_c} \frac{1}{|\Omega_c|} \sum_{H \subseteq F} 1$$

$$= \sum_H \sum_{F \in \Omega_c} \frac{1}{|\Omega_c|} \frac{|\Omega|}{|\Omega|}$$

$$= \frac{|\Omega|}{|\Omega_c|} \sum_H \Pr(F \supseteq H \text{ and } F \in \Omega_c)$$

$$= \frac{\Pr(F \supseteq H_0)}{\Pr(\Omega_c)} \sum_H \Pr(F \in \Omega_c | F \supseteq H)$$

$$= \frac{E(Z_H) \Pr(F \in \Omega_c | F \supseteq H_0)}{\Pr(\Omega_c)}. \quad (26)$$

So we will now compute $\Pr(F \in \Omega_c | F \supseteq H_0)$, by first computing the expected number of cycles of length $l$, conditional on $F$ containing $H_0$. Here $l$ can be considered fixed as $n \to \infty$.

To choose a cycle $C$ of length $l$, we will first fix $s$, the number of edges in $C \cap H_0$ (hereafter called $H$-edges), and $t$, the number of $H$-paths, i.e. the paths formed by the $H$-edges.

First we will count the number of ways to choose the edges of $C$ which will form the $H$-paths. Fix a starting vertex of $C$, and an orientation. We will
insist that the last edge of this orientation does not lie in an \( H \)-path. This will have the effect of multiplying the number of choices by \( 2(l - s) \). Now we will consider the generating function in which \( x, y, z \) mark the number of edges, \( H \)-edges, and \( H \)-paths respectively.

We go around the cycle and at each point we decide whether the next edge lies outside of \( H_0 \), an option we represent by \( x \), or if it is the first edge of an \( H \)-path, an option which we represent by \( x^{i+1}y^iz \) where \( i \) is the length of the \( H \)-path. Note that the first edge following the \( H \)-path must of course lie outside of \( H_0 \), explaining the exponent of \( x \). Thus we find that the number of choices of \( H \)-edges in \( C \) is (where as usual \( [x^ty^sz^t] \) stands for “coefficient of \( x^ty^sz^t \)):

\[
[x^ty^sz^t] \left\{ \frac{1}{2(l - s)} \left( x + \sum_{i \geq 1} x^{i+1}y^iz \right)^{l-s} \right\} = [x^ty^sz^t] \left\{ \frac{1}{2(l - s)} \left( x + \frac{x^2yz}{1-xy} \right)^{l-s} \right\}.
\]

Given such a choice, we now compute the number of ways to finish the cycle. The number of ways to choose the sequence of vertices in the cycle is \( \approx n^{l-s}2^t \). The number of choices for copies of those vertices is \( (r - 2)^{l-s+t}(r - 3)^{l-s-t} \). Also, the number of configurations containing \( H_0 \cup C \) is \( P((r-2)n - 2(l-s)) \), so we multiply by:

\[
\approx n^{l-s}2^t(r - 2)^{l-s+t}(r - 3)^{l-s-t} \\
\times P((r - 2)n - 2(l-s))/P((r - 2)n)
\]

23
\[ \approx \left( \frac{2(r-2)}{r-3} \right)^{(r-3)^{-s}(r-3)^t}, \]
to get
\[
[x^t y^s z^t] \frac{1}{2(l-s)} \left( (r-3)x + \frac{2(r-2)x^2yz}{1-xy} \right)^{l-s}
= -\frac{1}{2} [x^t y^s z^t] \ln \left( 1 - \frac{(r-3)x - \frac{2(r-2)x^2yz}{1-xy}}{} \right).
\]
(Observe that \((r-3)x + \frac{2(r-2)x^2yz}{1-xy})^k\) only contributes to terms of the form \(x^i (x^2yz)^{k-i} (xy)^j\) for some \(i, j\). So only \(i, j, k\) such that \(l = 2k - i + j, s = k - i + j\) and \(t = k - i\) affect our expression. But this implies that \(k = l - s\).

Summing over all \(s, t\) (or equivalently putting \(y = z = 1\), we get:

\[
-\frac{1}{2} [x^t] \ln \left( 1 - \frac{(r-3)x - x^2}{1-x} \right)
= -\frac{1}{2} [x^t] \ln \left( 1 - \frac{(r-2)x - (r-1)x^2}{1-x} \right)
= -\frac{1}{2} [x^t] (\ln(1+x) + \ln(1 - (r-1)x) - \ln(1-x))
= \frac{(r-1)^t + (-1)^t - 1}{2l}.
\]

Note that for \(l\) even, this is equal to the unconditional expected number of \(l\)-cycles in \(F\), explaining why we are concentrating on \(l\) odd. Let

\[
\mu_k = \frac{(r-1)^{2k-1} + (-1)^{2k-1} - 1}{2(2k-1)} = \lambda_k - \frac{1}{2k-1}.
\]
the expected number of cycles of length \(2k-1\) in \(F\) conditional on \(F \supseteq H_0\).
The next step is to compute
\[ E \left( [C_3]_{i_3} [C_5]_{i_5} \ldots [C_{2k-1}]_{i_{2k-1}} \mid F \ni H_0 \right) \]
for any fixed \( i_3, i_5, \ldots, i_{2k-1} \). This is done by counting the expected number of sets of \( i_3 \) distinct 3-cycles, \( i_5 \) distinct 5-cycles, ..., and \( i_{2k-1} \) distinct \( (2k-1) \)-cycles in \( F \), conditional on \( F \ni H_0 \). It follows from a straightforward first moment argument that \( F \) a.s. has no two intersecting cycles of length at most \( k \). It follows that the cycles appear almost independently, and we get:

\[ E \left( [C_3]_{i_3} [C_5]_{i_5} \ldots [C_{2k-1}]_{i_{2k-1}} \mid F \ni H_0 \right) \approx \prod_{j=1}^{k} \mu_j^{i_j}. \quad (27) \]

Therefore, conditional on \( F \ni H_0 \), the \( C_k \) are asymptotically independent Poisson variables with means \( \mu_k \). Hence, from (26),

\[ E_c \approx E(Z_H) \prod_{k=1}^{b} \left( \frac{\mu_k}{\lambda_k} \right)^{c_k} e^{\lambda_k - \mu_k}. \quad (28) \]

So,

\[ \sum_{c \in S(x)} \pi_c E_c^2 \approx E(Z_H)^2 \sum_{c \in S(x)} \prod_{k=1}^{b} \left( \frac{\mu_k^2}{\lambda_k} \right)^{c_k} e^{-\left(2\mu_k - \lambda_k\right)} \frac{c_k!}{c_k!} \]

\[ = E(Z_H)^2 \prod_{k=1}^{b} \lambda_k^{c_k} \sum_{c_k=0}^{\lambda_k^{2/3}} \left( \frac{\mu_k^2}{\lambda_k} \right)^{c_k} e^{-\left(2\mu_k - \lambda_k\right)} \frac{c_k!}{c_k!} \]

\[ = E(Z_H)^2 \prod_{k=1}^{b} (1 - Z_k) e^{\frac{(\mu_k - \lambda_k)^2}{\lambda_k}} \]

where

\[ Z_k = \sum_{c_k=\lambda_k^{2/3}}^{\infty} \left( \frac{\mu_k^2}{\lambda_k} \right)^{c_k} e^{-\left(\mu_k^2 / \lambda_k\right)} \frac{c_k!}{c_k!} \quad (29) \]

The following lemma appears in [13]
Lemma 3 Let $\eta_1, \eta_2, \ldots$ be given. Suppose that $\eta_1 > 0$ and that for some $c > 1, \eta_{i+1}/\eta_i > c$ for all $i > 1$. Then uniformly over $x \geq 1$,

$$R(x) = \sum_{i=1}^{\infty} \sum_{t=\eta_i(1+y_i)}^{\infty} \frac{\eta_i^t}{t! e^{\eta_i}} = O(e^{-c_0 x})$$

where $y_i = x \eta_i^{-1/3}$ and $c_0 = \min\{\eta_1^{1/3}, \eta_1^{2/3}\}/4$.

Applying this lemma with $\eta_i = \mu_i^2/\lambda_i$ and observing that $\eta_1 = (r - 3)^2/(2(r - 1)) \geq 6$ we see that

$$\sum_{k \geq 3} Z_k \leq O(e^{-x/20})$$

Hence, for $x$ sufficiently large,

$$\sum_{c \in S(x)} \pi_c E_c^2 \geq E(Z_H)^2(1 - be^{-x/20}) \prod_{k=1}^{b} \exp\left\{\frac{(\mu_k - \lambda_k)^2}{\lambda_k}\right\}.$$ (30)

Now,

$$\prod_{k=b+1}^{\infty} \exp\left\{\frac{(\mu_k - \lambda_k)^2}{\lambda_k}\right\} = \exp\left\{\sum_{k=b+1}^{\infty} \frac{2}{(2k-1)(r-1)^{2k-1}}\right\}$$

$$\leq \exp\left\{\frac{2}{(r-1)^{2b}}\right\}$$

$$\leq \left(1 - \frac{2}{(r-1)^{2b}}\right)^{-1}.$$ 

Thus, from (30), with

$$1 - \theta = \left(1 - be^{-x/20}\right) \left(1 - \frac{2}{(r-1)^{2b}}\right).$$
\[
\sum_{c \in S[x]} \pi_c E_c^2 \geq (1 - \theta) \mathbb{E}(Z_H)^2 \prod_{k=1}^{\infty} \exp \left\{ \frac{(\mu_k - \lambda_k)^2}{\lambda_k} \right\} \\
= (1 - \theta) \mathbb{E}(Z_H)^2 \exp \left\{ \sum_{k=1}^{\infty} \frac{2}{(2k - 1)(r - 1)^{2k-1}} \right\} \\
= (1 - \theta) \mathbb{E}(Z_H)^2 \left( \frac{r}{r - 2} \right).
\]

\[\square\]

**Proof of Lemma 1**

(a) Putting \(\eta_i = \lambda_i\) satisfies the conditions of Lemma 3 with \(c = 4/3\). Now

\[
\pi \leq \sum_{k=3}^{b} \sum_{c \geq \lambda_k(1+y_k)} \Pr(C_k = c) \\
\approx \sum_{k=1}^{b} \sum_{c \geq \lambda_k(1+y_k)} \frac{\lambda_k^c e^{-\lambda_k}}{c!} \\
= O(e^{-\alpha x}),
\]

for some constant \(\alpha\), independent of \(x\).

(b) Applying (28) we obtain

\[
E_c \approx \mathbb{E}(Z_H) \prod_{k=1}^{b} \left(1 - \frac{2}{(r - 1)^{2k-1}}\right) e^\lambda_k \exp \left\{ \frac{1}{2k - 1} \right\} \\
\geq AB^x,
\]

where

\[
A = \prod_{k=1}^{b} \left(1 - \frac{2}{(r - 1)^{2k-1}}\right) e^\lambda_k \exp \left\{ \frac{1}{2k - 1} \right\}
\]

and

\[
B = \prod_{k=1}^{b} \left(1 - \frac{2}{(r - 1)^{2k-1}}\right)^{\lambda_k^{2/3}}.
\]
Now

\[ A = \prod_{k=1}^{b} \exp \left\{ \frac{1}{2^k - 1} - \left( \frac{2\lambda_k}{(r - 1)^{2k-1}} + \frac{4\lambda_k}{2(r - 1)^{2(2k-1)}} + \cdots \right) \right\} \]

\[ \geq \prod_{k=1}^{\infty} \exp \left\{ -\frac{2\lambda_k}{(r - 1)^{2k-1}} \right\} \]

\[ = \exp \left\{ -\sum_{k=1}^{\infty} \frac{1}{(2k-1)(r - 1)^{2k-1}} \right\} . \]

The sum in the exponential term is convergent and so \( A \) is bounded below by a positive absolute constant.

Also

\[ B \geq \prod_{k=1}^{\infty} \left( 1 - \frac{2}{(r - 1)^{2k-1}} \right) \lambda_k^{2/3} \]

\[ \geq \exp \left\{ -\sum_{k=1}^{\infty} \frac{2}{(2k-1)^{2/3}(r - 1)^{2k-1}} \right\} . \]

Again, the sum in the exponential term is convergent and so \( B \) is bounded below by a positive absolute constant, completing the proof. \( \square \)
